4.0 Schedule

Preliminary, planning-level schedules were developed for the five landfill options as part of the landfill site engineering optimization. The schedules have been revised to include the results of the landfill preparation durations and are included as Figures 4-1 through 4-5. Table 4-1 provides a results summary.

TABLE 4-1

Landfill Preparation Schedule Summary

Construction Design Option	Landfill Preparation Component (years)	OMF South Completion	Contract Delivery Method
High Platform	2.8	Apr 2027	DB
Low Platform	3.2	Oct 2027	DB
Hybrid 1	3.2	Feb 2028	DBB/DB
Hybrid 2	2.7	Sept 2027	DBB/DB
Full Excavation	3.3	Dec 2028	DBB/DB

The schedule durations for the landfill preparation component in Table 4.1 generally consist of a combination of earthwork, landfill environmental controls, and shaft and slab installation activities, as applicable to each construction approach. These construction activities are generally overlapped as a result of the assumed construction phasing. Durations for the landfill preparation component of the overall construction schedule for each option will continue to be optimized as construction sequencing opportunities are further refined.

The preliminary schedule for each option assumes construction implementation through a design-bid-build (DBB) delivery for landfill preparation and design-build (DB) delivery for the OMF South building and track construction. Other schedule considerations pertaining to the landfill preparation are as follows:

1. The current target completion for the OMF South is 2026. None of the current Midway Landfill subsurface construction design options have a schedule that will meet this completion timeframe.
2. There may be an advantage in separating the landfill preparation construction from the OMF South construction. The landfill preparation could begin prior to completion of the OMF South design, which would provide an earlier construction start and result in earlier OMF South completion. An estimate of potential schedule benefit has not been prepared and is beyond the scope of this memorandum.

3. The construction contractor procurement process may require extension due to the complexity of the intermodal export and rail transport requirements. Establishing realistic bid pricing may require 6 months or more.
4. If improvements to an existing intermodal facility are required, or a new facility is required, then the schedule will be extended. It may be possible to have a reduced export rate initially, until intermodal facility construction is complete and full export can begin.
5. The schedule assumes construction phasing will provide enough flexibility and resiliency in the work to avoid delays due to changed conditions, such as encountered hazardous material.
6. The schedule assumes no significant environmental issues would be encountered that could stop the work, such as a landfill fire or contamination release.
7. The schedule assumes no significant rail transport disruptions that could stop the work.
8. The construction progress will be highly dependent on the construction contractor’s means and methods to plan and execute the work. Achievable performance requirements will need to be established in the construction contract.

5.0 Preliminary Landfill Preparation Cost Estimate

The preliminary, planning-level, rough order of magnitude (ROM) cost estimate pertains to additional work associated with the landfill preparation of each landfill redevelopment approach, including drilled shafts and slab work, as applicable. The cost estimate was prepared to compare the relative cost of the five options. The estimated costs were factored into the landfill site engineering optimization cost estimates to deliver the final project. Table 5-1 provides a summary of landfill preparation and final project delivery costs (in 2019 dollars) for each option. Table 5-2 includes detailed landfill preparation costs.

TABLE 5-1
Landfill Preparation Cost Summary

Construction Design Option	Landfill Preparation Cost	Total Project Cost (in M)
High Platform	$765,090,000	$1,529
Low Platform	$717,280,000	$1,477
Hybrid 1	$550,210,000	$1,295
Hybrid 2	$672,875,000	$1,429
Full Excavation	$748,538,000	$1,512

The estimated landfill preparation costs do not include the following:

1. Costs for mobilization and other construction preparation because these costs are in OMF South construction cost estimates.
2. Possible construction costs associated with the intermodal facility.
3. Costs to adjust OMF South design to address compatibility with the FWLE or modify FWLE.
4. Cost escalation.
5. Design and construction management costs for the landfill preparation.

The Total Project Costs do not include costs associated with connection to the FWLE or modification requirements to FWLE.

TABLE 5-2

Detailed Landfill Preparation Costs

			High Structural Platform		Low Structural Platform		Hybrid 1		Hybrid 2		Full Excavation	
Item	**Unit**	**Unit Price**	**Quantity**	**Cost**	**Quantity**	**Cost**	**Quantity**	**Cost**	**Quantity**	**Cost**	**Quantity**	**Cost**

[1] Capping system costs include stormwater management and other general construction aspects associated with landfill closure.

6.0 Compatibility with the Known Status of FWLE Construction

If constructed at Midway Landfill, the OMF South will connect to the mainline of the FWLE. The current FWLE mainline design is not at an elevation and grade to allow direct connections to the proposed OMF South lead tracks. The five OMF South landfill options have been designed with the yard at elevations 365 feet (Hybrid 1, Hybrid 2, and Full Excavation), 380 feet (Low Platform), and 408 feet (High Platform). The FWLE will follow the general grade of I-5, while the OMF South will be flat.

There are currently five proposed track connections between the FWLE and the OMF South. To minimize the extent of mainline modification, a third track is proposed running alongside the mainline at an elevation closer to the selected OMF South elevation for compatibility with the yard-connecting tracks. The third track would have a connection to the mainline at the north and south ends only. The connection track would have No. 10 turnouts and be designed for 25 miles per hour. The connecting tracks and yard lead tracks would require a design variance for all vertical curve lengths. There are independent vertical track designs for each of the three OMF South elevation options.

Based on the current FWLE mainline design, irrespective of the construction option selected, the FWLE mainline will need to be modified to enable the connection of OMF South lead track turnouts at the required grade of 2% or less (DCM Rev 5). The extent of mainline modification varies based on the OMF South site elevation, as shown in Table 6-1 below.

TABLE 6-1
Track Summary

	Low Yard Elevation (365')	Medium Yard Elevation (380')	High Yard Elevation (408')
Northern Mainline Modifications*	Up to approximate 8' rise in elevated mainline over 3,200'.	Up to approximate 8' rise in elevated mainline over 3,200'.	Up to approximate 8' rise in elevated mainline over 3,200'.
Southern Mainline Modifications*	Up to approximate 10' lowering of at-grade mainline over 1,900'.	Up to approximate 5' lowering of at-grade mainline over 1,900'. Potential to avoid southern mainline modifications through further optimization.	Up to approximate 5' lowering of at-grade mainline over 1,900'. Potential to reduce southern mainline modifications through further optimization.
Connecting/Third Track**	At-grade connecting track. Steep grades (~6%) and significant cut toward south end. Vertical curve length design variance required.	At-grade connecting track. Moderate grades. Vertical curve length design variance required.	Elevated connecting track. Moderate grades. Vertical curve length design variance required.
Lead Tracks	At-grade lead tracks. North lead track has steep grades (~6%). Vertical curve length design variance required.	At-grade lead tracks. Moderate grades. Vertical curve length design variance required.	Elevated lead tracks connect elevated connecting track to high yard platform. Moderate grades. Vertical curve length design variance required.
Constructability	More complex. Requires deep cut of existing landfill.	Least complex.	More complex. Elevated lead tracks connect elevated connecting track to high yard platform. Complex elevated construction.
Cost	$$$$	$$$	$$$$
Schedule	Potential longer duration.	Medium duration.	Potential longer duration.

*Mainline modifications could be significantly reduced with design variance, allowing turnouts to be placed on greater than 2% grade.

**Connecting track minimizes mainline modifications but limits mainline connections to two locations. Further potential to eliminate third track to reduce lead track lengths and mainline modifications, with some operational impact.

7.0 Potential Settlement

The five options to redevelop the Midway Landfill as the OMF South will have different performance implications pertaining to potential future settlement. Site settlement will have a significant negative impact on the OMF South operation due to light rail tolerances.

Landfilled material will continue to consolidate over time due to the compressive nature of the material, overburden weight, and biodegradation of the material. Settlement will likely be differential, or uneven, throughout a landfill as a result of variable refuse thickness and heterogenus composition of the material. The differential settlement can negatively impact the integrity of building foundations, utilities, roadways, and trackways. The settlement evaluation provided by the Preliminary Geotechnical Engineering Services Report Revised, by GeoEngineers, estimates that the current landfill could have differential settlements ranging from 2 to 12 inches over the next 10 to 15 years.

The five options provide alternative designs to mitigate potential settlement as follows.

High Platform: This option will be designed to support the OMF South buildings and track on drilled shafts into competent native ground below the landfill.

Low Platform: This option will be designed to support the OMF South buildings and track on drilled shafts into competent native ground below the landfill. The option shortens the height of drilled shafts, further increasing stability.

Hybrid 1: This option removes overburden material, which will help offset the compressive loading of the OMF South on the refuse below. The option also removes a portion of the refuse mass below the facility. This will reduce the amount of degradable material. Dynamic compaction of the remaining refuse material will be intended to further compress the material and reduce future settlement. The competent backfill material thickness will help reduce differential settlement of the refuse below, creating a more uniform settlement result. Buildings will be supported on shafts drilled into the competent native ground below the landfill and the track will be supported on improved subgrade. The remaining refuse under the yard areas will have settlement implications due to material degradation and consolidation, potentially requiring operational adjustments to the yard ballast material supporting the tracks and at yard area interfaces with areas not subject to settlement.

Hybrid 2: This option removes overburden material, which will help offset the compressive loading of the OMF South on the refuse below. The option also removes a portion of the refuse mass below the facility. This will reduce the amount of degradable material. Dynamic compaction of the remaining refuse material will be intended to further compress the material and reduce future settlement. The competent backfill material thickness will help reduce differential settlement of the refuse below, creating a more uniform settlement result. Buildings will be supported on shafts drilled into the competent native ground below the landfill and the track supported on an on-grade concrete slab over improved subgrade. The remaining refuse under the yard areas will have settlement implications due to material degradation and consolidation. The provision of an on-grade concrete slab in the yard areas will further mitigate differential impacts; however, impacts may become more pronounced at slab joints and interfaces.

Full Excavation: This option removes the degradable material from the refuse mass and backfills the OMF South subgrade with competent material. Building and track will be supported by the backfilled subgrade. The option should eliminate settlement due to degradation. The depth of fill and irregularity of the large quantity of reused competent landfill material provides potential for long-term consolidation settlement.

Based on the settlement tolerance guidance from Sound Transit, all five options to redevelop the Midway Landfill will be designed to meet the long-term settlement of 1 inch over a period of 50 years, using the data analysis from planned geotechnical borings at the site. The High Platform and Low Platform options and the building portions of Hybrid 1 and Hybrid 2 options will be designed on drilled shafts to prevent settlement greater than 1 inch over a period of 50 years. The deep dynamic compaction associated with the track portions of Hybrid 1 and Hybrid 2 options is expected to have a design specification that will result in waste material compaction such that the long-term settlement of the compacted waste and overlying granular backfill would be less than 1 inch over a period of 50 years. For the Full Excavation option, the granular backfill will require compaction such that the long-term settlement would be less than 1 inch over a period of 50 years.

8.0 Conclusions and Next Steps

This interim memorandum is a high-level discussion of landfill preparation considerations pertaining to the potential redevelopment of the Midway Landfill as the OMF South. The evaluation is presented as possible approaches to the work to better inform decision-making. Assumptions and influencing factors will be dependent on construction contractor means and methods and other project factors.

A construction option evaluation matrix was developed for the five landfill options based on the evaluation sections above. The matrix is included as Table 8-1 and provides a Low (RED), Medium (YELLOW), High (GREEN) rating relative to each construction approach and category. The intent of the matrix is to provide a visual assessment of which subsurface construction design options may stand out as being potentially the most viable for further evaluation in Sound Transit's forthcoming Draft EIS.

Further consideration for the redevelopment of the Midway Landfill site as the OMF South is expected to include confirmation of more assumptions, consideration of upcoming landfill geotechnical and environmental site investigations, and constructability review of the landfill preparation options by a qualified construction contractor.

8.1 Confirm Assumptions

The evaluation of Midway Landfill redevelopment will continue in accordance with Task 9.3.1.16 – Engineering, Solid Waste Engineering, and Task 9.8 – Detailed Evaluation of Landfill Site Reuse. As these tasks are advanced, engineering and regulatory assumptions within this memorandum will continue to be refined to provide a more accurate understanding of the potential options.

Some assumptions are dependent upon construction contractor means and methods for planning and executing the work and will continue to have some uncertainty associated with them until an eventual construction contract is awarded.

8.2 Landfill Investigations

Additional geotechnical borings are being planned at the landfill. These borings may provide some insight into:

1. Depth of clean cover soil,
2. Landfill density,
3. Landfill depth,
4. Percentage of reusable material recoverable through screening,

TABLE 8-1

Subsurface Construction Design Options Evaluation Matrix[1]

Subsurface Construction Design Options	**OMF South Settlement Mitigation**	**Environmental Protection**	**Ease of Material Disposal**	**Ease of Construction Phasing**	**Low Traffic Impacts**	**FWLE Compatibility**	**Least Schedule Impacts**	**Least Additional Cost[2]**
Methods	Assessment of the option's ability to reduce future risk of settlement. High (Green) = Mitigation based on structural design, Medium (Yellow) = Mitigation susceptible to remaining refuse and/or reuse material, Low (Red) = Minimal mitigation	Assessment based on reduced risk of exposure to environmental hazards. High (Green) = Minimal contaminants handling and exposure, Medium (Yellow) = Significant onsite contaminants handling and exposure, Low (Red) = Significant onsite and offsite contaminants handling and exposure	Assessment of amount of material requiring offsite export and disposal. High (Green) = Less than 500,000 tons, Medium (Yellow) = Between 500,000 tons to 2,500,000 tons, Low (Red) = More than 2,500,000 tons	Assessment of construction complexity. High (Green) = Some excavation without screening and reuse, Medium (Yellow) = Moderate excavation depth with screening and reuse, Low (Red) = Deep excavation with screening and reuse	Assessment of traffic impacts based on PCEs. High (Green) = Less than 50 PCEs, Medium (Yellow) = Between 51 and 90 PCEs, Low (Red) = Greater than 90 PCEs.	Assessment of complexity for connection to FWLE. High (Green) = Most compatible with FWLE, Medium (Yellow) = Moderately compatible with FWLE, Low (Red) = Least compatible with FWLE	Ability to best meet the original 2026 scheduled facility opening. High (Green) = Opening within 1 year of 2026 target, Medium (Yellow) = Opening within 2 years of 2026 target, Low (Red) = Opening later than 2 years of 2026 target	Assessment of order of magnitude landfill preparation cost. High (Green) = Less than $500 million, Medium (Yellow) = Between $500 million and $700 million, Low (Red) = Greater than $700 million
High Structural Platform with No Excavation	🟩 Designed as elevated platform on shafts founded in competent material	🟩 Minimally invasive into the landfill, elevated platform with reduced landfill gas exposure	🟩 Less than 200,000 tons of export to a landfill	🟩 Least amount of landfill excavation	🟩 Passenger car equivalency would not significantly degrade operating conditions	🟥 OMF lead tracks need to be elevated , increased complexity and cost	🟩 Exceeds target 2026 opening by approximately <1 year	🟥 Over $700 million in landfill preparation costs
Low Structural Platform with Some Excavation	🟩 Designed as elevated platform on shafts founded in competent material	🟨 Significant refuse handling, facility interface with landfill surface	🟩 Less than 100,000 tons of export to a landfill	🟩 Limited work area, low depth of excavation, material screening not required	🟩 Passenger car equivalency would not significantly degrade operating conditions	🟩 At grade connection, moderate grades, least complexity and cost	🟩 Exceeds target 2026 opening by approximately <1 year	🟥 Over $700 million in landfill preparation costs
Hybrid 1: Excavation with Ground Improvements (Buildings on Drilled Shafts)	🟨 Refuse remains in the subgrade, settlement mitigation, reuse material	🟥 Significant refuse handling and export, facility interface with landfill surface	🟥 Approximately 3 million tons of export to a landfill	🟨 Limited work area, moderate depth of excavation	🟥 Passenger car equivalency would degrade northbound operating conditions	🟨 At grade connection, steep grades, increased complexity and cost	🟨 Exceeds target 2026 opening by approximately <2 year	🟨 Over $500 million in landfill preparation costs
Hybrid 2: Excavation with Ground Improvements (Slab on Grade for Tracks and Buildings on Drilled Shafts)	🟨 Refuse remains in the subgrade, settlement mitigation, reuse material, slab added to mitigate differential settlement	🟥 Significant refuse handling and export, facility interface with landfill surface	🟨 Approximately 2 million tons of export to a landfill	🟨 Limited work area, moderate depth of excavation	🟨 Passenger car equivalency would somewhat degrade northbound operating conditions	🟨 At grade connection, steep grades, increased complexity and cost	🟩 Exceeds target 2026 opening by approximately <1 year	🟨 Over $600 million in landfill preparation costs
Full Excavation and Backfill with Competent Soils	🟨 Deep fill, reuse, and import material	🟥 Significant refuse and wastewater handling and export, facility interface with landfill surface, reduced landfill gas generation	🟥 Approximately 4 million tons of export to a landfill	🟥 Limited work area, greatest depth of excavation	🟥 Passenger car equivalency would degrade northbound operating conditions	🟨 At grade connection, steep grades, increased complexity and cost	🟨 Exceeds target 2026 opening by approximately <2 year	🟥 Over $700 million in landfill preparation costs

[1] Relative comparison between subsurface construction design options at the Midway Landfill. The comparison is not inclusive of other potential OMF South sites.

[2] Cost comparisons do not include costs associated with FWLE connection or modifications required to FWLE.

5. Potential for irregular or hazardous material, and
6. Depth to groundwater.

LFG will also be assessed with regard to human health risk. The temporary penetrations resulting from the geotechnical investigation, LFG probes and wells, and LFG flare inlet will be sampled for methane and contaminants of concern. These data will be used in comparison with historical data to develop a better understanding of current contamination levels within the landfill.

8.3 Constructability Review

A qualified earthwork contractor will evaluate the five options and assumptions to provide a contractor means and methods perspective for planning and executing the work. The industry constructability insight will assist in confirming or refining the assumptions to develop a comprehensive understanding of the requirements associated with each approach.

8.4 Final Landfill Preparation Memorandum

Information pertaining to landfill site reuse beyond the preparation of this memorandum will be documented in a Conceptual Landfill Site Reuse Plan, planned for delivery to Sound Transit in June 2020. The plan will cover the options Sound Transit determines to carry forward for documentation in the project's Draft EIS. The plan will document the evaluation process and discuss the potential property transaction, permitting, schedule, design, risk, health and safety, unknowns, and other considerations that will continue to be developed under Task 9.8 – Detailed Evaluation of Landfill Site Reuse.

1.0 Introduction

1.1 Project Description

Sound Transit proposes to construct and operate an operations and maintenance facility (OMF) to meet agency needs for an expanded fleet of light rail vehicles (LRVs) identified in *Sound Transit 3: The Regional Transit System Plan for Central Puget Sound*. The Sound Transit Operations and Maintenance Facility South (OMF South) project would be used to store, maintain, and deploy about 144 LRVs for daily service. It would provide facilities for vehicle storage, inspections, maintenance and repair, interior vehicle cleaning, and exterior vehicle washing. Additionally, the facility would receive, test, and commission new LRVs for the entire system.

OMF South would also be used to accommodate administrative and operational functions, such as serving as a report base for LRV operators. Included is a Maintenance of Way (MOW) building for maintenance and storage of spare parts for tracks, vehicle propulsion equipment, train signals, and other infrastructure in addition to storage facilities for the entire Link system. Other facility elements would include employee and visitor parking; operations staff offices; maintenance staff offices; dispatcher work stations; an employee report room; and areas with lockers, showers, and restrooms for both operators and maintenance personnel.

OMF South would need to have tracks connecting to an operating light rail mainline, which in southern King County is the Federal Way Link Extension (FWLE). The length and location of these connecting tracks varies by site alternative.

Three site alternatives for the proposed project are being evaluated in the Draft Environmental Impact Statement: one in Kent and two in Federal Way. These alternatives are named the Midway Landfill Alternative, South 336th Street Alternative, and South 344th Street Alternative, respectively. This plan is focused on the Midway Landfill Alternative.

1.2 Purpose

The Midway Landfill is currently being evaluated as one of three site alternatives in the Draft Environmental Impact Statement for the OMF South project.

The subsurface development of OMF South under the Midway Landfill Alternative will require unique design considerations for remedial environmental controls and to protect the facility against settlement. Landfill-specific design considerations are not required at the other OMF South site alternatives. Three landfill subsurface construction design options (options) are currently being explored for the Midway Landfill Alternative, as described in Section 2.6.

Previously, the Interim Midway Landfill Preparation Memorandum (Sound Transit 2020b) completed in February 2020 studied five options:

1. High Platform – High Structural Platform with No Excavation
2. Low Platform – Low Structural Platform with Some Excavation
3. Hybrid 1 – Excavation with Ground Improvements (Buildings on Drilled Shafts)
4. Hybrid 2 – Excavation with Ground Improvements (Slab on Grade for Tracks and Buildings on Drilled Shaft)
5. Full Excavation – Full Excavation and Backfill with Competent Soils

The five options identified in the Interim Midway Landfill Preparation Memorandum have been reduced to three options that address a reasonable and broad range of options for further study in this plan:

1. Low Platform – Low Structural Platform with Some Excavation
2. Hybrid 2 – Excavation with Ground Improvements (Slab on Grade for Tracks and Buildings on Drilled Shaft)
3. Full Excavation – Full Excavation and Backfill with Competent Soils

With the exception of cost, schedule, and legal considerations, this plan provides a comprehensive summary of the landfill-specific assessments performed to date in consideration of the Midway Landfill Alternative for the OMF South site. The assessments include regulatory considerations and permitting; landfill preparation requirements; functional design options, including settlement mitigation; operational health and safety; and remaining risks and unknowns. Cost and schedule of the three design options for the Midway Landfill, as well as legal considerations, will be assessed as part of a future process and included in the Basis of Design. Cost and schedule risks for the three design options are discussed in this plan.

This plan advances the findings of the Interim Midway Landfill Preparation Memorandum (Sound Transit 2020b) and summarizes other landfill-specific assessment deliverables to inform the Sound Transit decision-making process during the siting evaluation.

1.3 Midway Landfill Background

The Midway Landfill is a Superfund site owned by the City of Seattle and managed by Seattle Public Utilities (SPU). It is regulated by the U.S. Environmental Protection Agency (EPA) and the Washington State Department of Ecology (Ecology) under an existing Consent Decree and Record of Decision (ROD).

As discussed in the Consent Decree, the Midway Landfill was originally a gravel pit, which was operated from 1945 to 1968. SPU began landfill operations at the site in 1966 primarily to accept demolition-type wastes. Landfill operations continued until 1983, when the facility was closed. Approximately 3 million cubic yards (cy) of solid waste, reported to include primarily demolition materials and wood waste, were deposited at the unlined landfill facility. Refuse depths in some areas are up to 130 feet.

Concerns for negative impacts to human health and the environment were identified in 1983 by SPU (when the landfill was closed). Environmental testing indicated landfill gas (LFG) outside the landfill’s boundary, and organic and inorganic contaminants were found in groundwater.

An active LFG management system was installed in 1985, and in 1986 the Midway Landfill was placed on the National Priorities List (NPL) due to the groundwater contamination. Listing the site on the NPL provided the EPA with responsible oversight of the facility. Pursuant to the Model Toxics Control Act (MTCA), SPU entered into a Consent Decree with Ecology in 1990 to initiate cleanup work.

A final remedy for the site was identified in a ROD by EPA, with Ecology’s concurrence, on September 6, 2000. The identified remedy’s aim was to ensure that refuse containment is effective and maintained, groundwater quality is restored beyond the landfill boundary, and no residential exposure to landfill groundwater occurs until standards have been met.

SPU completed landfill closure construction in 1992; however, since the ROD was not signed at that time, construction completion was not officially recognized until September 21, 2000.

SPU has continued to manage and maintain the site with regular environmental reporting, including required Five-Year Review Reports by the EPA and Ecology completed in years 2005, 2010, and 2015.

The Midway Landfill is approximately 60 acres in size with buried refuse on approximately 45 of those acres. The site is situated west of Interstate 5 (I-5) and east of Highway 99 (Pacific Highway South, or State Route [SR] 99) and bounded by residences on the north and south. Some commercial areas are located between SR 99 and the landfill. Based on a February 2007 reuse planning report (City of Seattle 2007) for the Midway Landfill, the landfill reuse potential was summarized as follows:

- Four acres of the site have no refuse and minimal remedy components. These acres front SR 99 and have potential for unrestricted uses in the near term.
- Seven acres have shallow (approximately 50 to 60 feet deep) refuse and have minimal surface remedy components. These acres could potentially be used for surface uses such as a parking lot or active recreation in the future.
- Fourteen acres house the site’s LFG flare station and stormwater retention pond, and these will need to remain and be operational into the foreseeable future.
- Nine acres comprise the Washington State Department of Transportation (WSDOT) right-of-way (ROW) that will be used in the future for an I-5 roadway widening for the SR 509 project. Some volume of solid waste is presumed buried on the western edge of this ROW.

- Thirty-seven acres have waste that is moderately or deeply (up to and greater than 90 feet deep) located and have extensive surface remedy components. Alternate land uses in the future may be possible in the long term.

The general fill topography of the landfill provides an elevated, irregular surface that is sloped to drain to steeper side slopes. Components and facilities at the site generally include:

- Landfill Cap: Layers from bottom to top include a 12-inch-thick layer of low permeability (1 x 10^{-7} centimeters per second) soil/clay material, a 50-mil-high density polyethylene (HDPE) geomembrane, drainage geonet, geotextile, a 12-inch-thick drainage layer, and a minimum 12-inch-thick topsoil layer. See Figure 1-1 for the landfill cap section.

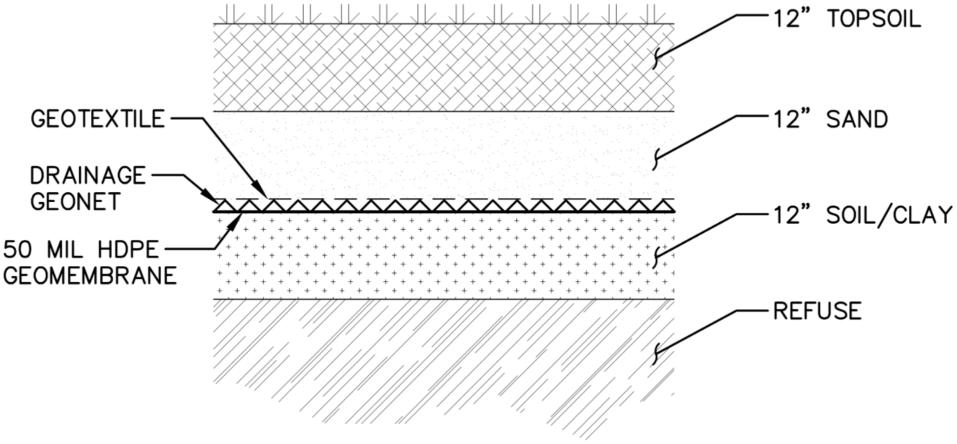

Figure 1-1. Existing Landfill Cap Section

- Landfill Surface Filling and Grading: 2 to 14 feet of soil cover over the refuse.
- The landfill cap is maintained in good condition but continues to experience differential settlement.
- Stormwater Detention: A 3-acre, 60-mil HDPE geomembrane-lined stormwater detention pond to collect landfill runoff and contributions from other areas/facilities. The pond base is below the groundwater level and has a permanent dewatering system. The pond has a discharge line to a downstream system.
- LFG System: LFG is routed to the on-site LFG flare station through header pipes.
    - 87 LFG extraction wells (56 on site and 31 off site). The off-site extraction wells have since been abandoned.
    - 70 off-site LFG monitoring probes (approximately 35 probes have been abandoned).

- Groundwater Monitoring System: The system currently includes wells for water level measurements (68 wells) and groundwater chemistry monitoring (15 wells).

1.4 OMF South Background

OMF South will store, maintain, and deploy a fleet of LRVs. OMF South will service the south and central corridor as the system wide fleet expands to more than 400 total LRVs to serve future expansion and growth in system wide ridership.

The site for the proposed OMF South needs to have the capacity to store and maintain over 144 LRVs. OMF South would contain light rail storage tracks as well as buildings, parking, storage areas, internal roads, landscaping, fencing, setbacks, stormwater facilities, electric transmission lines, and other utilities. OMF South also includes a 5-acre area for maintenance and yard storage, which includes vehicles, equipment, and a 30,000-square-foot building. OMF South needs to have tracks connecting to a light rail line. For the Midway Landfill Alternative, that light rail line is the FWLE.

A more complete description of OMF South physical and functional requirements is available in the Conceptual Basis of Design Report (Sound Transit 2020a). The conceptual site layout of the OMF South facility at the Midway Landfill is shown in Figure 1-2.

OMF South Conceptual Site Layout

2.0 Landfill Site Reuse Evaluation

The landfill site reuse evaluation provides initial reuse analyses to gain an improved understanding of the potential impacts of undertaking the construction of OMF South at the Midway Landfill. The evaluation focuses on the following primary elements:

1. Landfill redevelopment feasibility,
2. Regulatory requirements,
3. Experiences at other landfill/contaminated sites,
4. Human health risk assessment,
5. Landfill site engineering and optimization, and
6. Landfill preparation requirements

2.1 Landfill Redevelopment Feasibility

The landfill redevelopment feasibility assessment introduced preliminary technical and regulatory considerations of locating OMF South on a closed landfill site and identified benefits, challenges, and risks associated with this kind of development. The assessment provided a brief background on the typical landfill life cycle and the characteristics of an older, closed landfill. The Midway Landfill was assessed based on available documents to understand the physical nature of the site and the currently imposed environmental and regulatory requirements.

A high-level review of early OMF South conceptual layouts was applied to the site. Considerations for redevelopment design and constructability were discussed, followed by some considerations for site operation and long-term maintenance requirements and potential future Sound Transit employee safety and health considerations. The study also included potential schedule impacts and a review of other facilities that have been redeveloped at landfills or otherwise contaminated sites. Cost considerations were not a component of this early study.

The study was documented in the OMFS Landfill Evaluation Report (Sound Transit 2019a). Following is a brief summary of the findings:

- Based on the evaluation conducted during the study, no criteria had been identified that would eliminate the Midway Landfill with certainty from further consideration for OMF South. Preliminary research into redevelopment projects at Superfund and/or state-led contaminated sites – in particular, other landfill sites – indicated that design and construction of a facility on a closed landfill could be a viable alternative. The fact that the site is a former landfill under state and federal regulatory oversight should not preclude it from continued consideration.

- Preliminary discussions with the property owner and regulators, review of regulatory requirements, and development of assumptions around anticipated site improvements at that time had not identified any major impacts to the design or construction schedule to preclude the OMF South project from being developed on the closed landfill. Potential landfill-related permitting dynamics and site preparation (in advance of construction) would likely be required but could be possible within the overall project schedule provided that they are considered proactively as part of overall design and construction strategy.
- More detailed research into both successful and challenging redevelopment examples at similar sites may provide information that could help inform the design process. It could also circumvent potential challenges previously faced by other landfill and contaminated site redevelopment projects around the country. This research would provide greater insight on cost implications, constructability, geotechnical considerations, and worker health and safety concerns, during both construction and operation.
- A land use attorney with Superfund-related experience should be consulted by Sound Transit to fully understand the retained and transferred liabilities associated with a potential agreement for use of the site. Prior to construction, Sound Transit may consider working with SPU and the governing agencies to proactively establish procedures for evaluating conditions during and after construction to demonstrate that redevelopment activities have resulted in no new impacts at the site.
- Development of OMF South on a closed landfill would require specific design approaches, construction technologies, and modifications to existing environmental controls. For example, the redevelopment conceptual designs for the Midway Landfill at the time of the study would construct OMF South on a reinforced concrete pile-supported platform (Phase 1, High Platform option). The platform would be elevated over the landfill to avoid landfill settlement impacts to OMF South and lessen impacts to the landfill remedial systems. Proactive communication with property owner and regulators, development of a contextual design approach consistent with the regulatory requirements, and efficient construction sequencing would be required to reduce impacts to the design and construction schedule for the development on a closed landfill relative to the overall OMF South project.
- Initial review of employee health and safety considerations indicates there would be limited exposure possibilities to contaminated groundwater and LFG. It will be critical for landfill redevelopment to maintain the existing environmental controls (i.e., LFG

collection system) to limit exposure pathways. Inclusion of additional preventative measures such as building foundation barriers, active and passive ventilation, and continuous methane monitoring in interior workspaces would likely be included in future facility design in addition to the remedial systems associated with the closed landfill. (More details on human health and safety are discuss in Section 2.4 of this plan.)

2.2 Regulatory Requirements

As identified in Section 1.2, the Midway Landfill Alternative possesses unique regulatory considerations due to the environmental liabilities associated with the landfill and its status as a Superfund site.

The Midway Landfill Site is listed as a federal Superfund Site under the National Priorities List. Under a cooperative agreement between EPA and Ecology, and as provided in the ROD, Ecology is the designated lead regulatory agency overseeing the Site and performance of the selected remedial action. The ROD, 5-year reviews, and the recently adopted Cleanup Action Plan Amendment No. 1 (for the FWLE project) identify the Applicable or Relevant and Appropriate Requirements (ARARs), which are the regulatory programs applicable to the former landfill and Site that any cleanup action must demonstrate compliance with under MTCA and the Comprehensive Environmental, Response, Compensation, and Liability Act (CERCLA).

The primary basis of action under the ROD is groundwater contamination above federal drinking water standards. Original contaminants of concern (COCs) include 1,2-dichloroethane, vinyl chloride, and manganese. During the 2010 to 2015 5-year review period, 1,4-dioxane was detected above MTCA Method B levels and is also considered a potential COC. The OMFS Landfill Evaluation Report (Sound Transit 2019a) provides additional details pertaining to current COCs and required cleanup levels at Midway Landfill.

An established protective remedy is in place at the site, which is reviewed every 5 years during the EPA’s standard 5-year review process. The intent of the remedy required by the ROD, in accordance with the requirements of CERCLA of 1980, is to protect human health and the environment, specifically:

- To ensure containment is effective and working. Though not explicitly stated in the ROD, containment refers to containment of the waste by a landfill cap, prevention of surface water infiltration through the landfill cap, and containment of LFG through the LFG extraction system.
- To ensure containment will be maintained when and if major changes are approved by Ecology in operation of the site.
- To return groundwater to drinking water standards and state cleanup standards downgradient of the landfill boundary.

- To ensure no residential exposure to groundwater until groundwater cleanup standards have been met.

Institutional controls require that operation and maintenance of the containment and monitoring systems must continue if the ownership or control of the property should change.

Significant changes to the existing remedies implemented at the landfill would need to be approved by Ecology, in coordination with EPA. Any potential changes would need to maintain the integrity of the remedy and required under the ROD and the Consent Decree. Major changes to the approved remedy could have the potential of reopening of the ROD and resulting in additional administrative and project scheduling challenges.

For the FWLE project, Ecology, in consultation with EPA, issued a Cleanup Action Plan Amendment (CAP Amendment) to describe the cleanup activities required at the site as part of the project. Ecology simultaneously entered into Consent Decrees with SPU (Consent Decree Amendment) and Sound Transit (Prospective Purchaser Consent Decree) to require compliance with the CAP Amendment and address other issues under MTCA. A similar sequence of activities, i.e., CAP Amendment and Consent Decrees, may be applicable for the OMF South project, pending further coordination with Ecology and EPA.

Regulatory coordination with major project stakeholders has already initiated on the potential for siting OMF South on the Midway Landfill. The OMF South project has begun coordinating with EPA and Ecology.

In 2018, Sound Transit met independently with representatives of both EPA and Ecology to discuss the potential development of OMF South at the Midway Landfill. As the lead regulatory agency for Midway Landfill, Ecology will have review and approval authority for any planned operational changes at the site. Based on the discussions in that meeting, if EPA approves the project under Superfund, the development process for Midway Landfill may be exempt from the requirement of the National Environmental Policy Act (NEPA). In addition, the existing ROD may not need to be reopened, if during the course of OMF South construction, the integrity of the existing, in-place remedies are maintained. It should be noted that a NEPA process for the project may be required by the Federal Highway Administration (FHWA) for airspace crossing of WSDOT land or other reasons outside the scope of this landfill evaluation.

In October 2019, Sound Transit and the broader project team, including SPU, met with Ecology to provide the regulators with an update of the OMF South project and redevelopment strategies being considered for Midway Landfill and to discuss the regulatory path forward if the project were advanced at the site. At the time, five subsurface construction options were being considered, as discussed in Section 2.5. Detailed information on the five options is available in the Midway Landfill Site Engineering Optimization Report (Sound Transit 2019b).

General feedback received by Sound Transit from Ecology pertaining to the redevelopment of Midway Landfill as OMF South was as follows.

- Removal and replacement of the landfill cap is feasible provided the project can demonstrate the ability to control the site and mitigate risks associated with construction methodologies consistent with the existing ROD and Consent Decree. Methodologies must be protective of human health and the environment.
- Ecology would be supportive of the redevelopment and provide resources to try to facilitate Sound Transit's schedule; however, no regulatory review durations were expressed.
- Ecology would allow reuse of solid waste on site.
- Ecology was accepting of the subsurface construction approaches presented provided they are implemented in a protective manner.
- The regulatory process was expected to be similar to the Midway Landfill work associated with FWLE, which required an amendment to the CAP and simultaneous Consent Decrees.

The Seattle-King County Department of Public Health will need to be provided the opportunity to review requested operational changes at the site.

From a project management perspective, regulatory coordination could be assessed as most significant for the Midway Landfill Alternative in its potential to impact project delivery. Significant schedule impacts come from incorporating the timelines associated with development of the legal documents, including CAP and ROD Amendments and Consent Decrees, into the OMF South project schedule. The main timing issue with the additional environmental agreements and approvals relates to the inability of the project to begin ground-disturbing activities on site to prepare for construction of the OMF building prior to agency adoption of the CAP and/or ROD Amendments, judicial entry of the Consent Decrees, and finalization of other agreements. Timing for adoption of the CAP and/or ROD Amendments, entry of the Consent Decrees, and finalization of other agreements is currently estimated to be approximately 1 year if led by Ecology, and approximately 2 years if led by EPA, starting after Preferred Alternative identification for the project in 2021. Ecology is currently anticipated as the lead agency. Construction is anticipated to begin in 2023 with operations beginning in the late 2020s.

If the Midway Landfill Alternative is advanced, ongoing and effective coordination with Ecology and EPA will be needed to ensure that the regulatory agencies are informed about the proposed design and construction approach and are prepared to approve the proposed environmental controls to be implemented during construction and at facility completion through CAP and/or ROD Amendments. Feedback will be needed from these agencies to determine what regulatory requirements will be prompted by the proposed approaches and to identify if there is an approach that may be preferable from a regulatory standpoint. Additional outcomes will be to determine a realistic approval process, approval requirements, and project milestone schedule.

A key objective of this communication will be to maintain the work within the existing regulatory framework (i.e., ROD). Additionally, acceptable construction approaches will need confirmation to determine landfill preparation impacts to the schedule and cost of the project. Current assumptions pertaining to landfill preparation requirements are discussed in Section 2.6.

Furthermore, to operate a future OMF within the City of Kent, Sound Transit would also need to develop and execute a Transit Way Agreement with the City of Kent to grant Sound Transit the right to own, operate, and maintain transit facilities in the public ROW within the City of Kent. And lastly, Sound Transit would need to negotiate and execute a Development Agreement (DA) with the City of Kent or apply for and receive a Conditional Use Permit (CUP) to establish land use and permit the OMF South construction. A DA, or CUP, would outline applicable city code requirements and development standards and would allow code departures and any required project mitigation in addition to any mutually agreed-upon enhancement partnerships related to multimodal access or otherwise. The City of Kent permitting requirements are not unlike the requirements of the other two site alternatives in Federal Way.

2.3 Experiences at Other Landfill/Contaminated Sites

Potential similar sites were researched on a limited basis to attempt to gain an understanding of the experiences of others and lessons learned that could inform and improve the OMF South design and operation if constructed at the Midway Landfill. The research could also provide insights on regulatory considerations, construction technologies, assessments related to public/employee health and safety, and monitoring. A similar site was generally considered a redeveloped contaminated site with an emphasis on rail transit and landfills.

The initial review of other landfill/contaminated sites that were redeveloped was performed as part of the OMFS Landfill Evaluation Report (Sound Transit 2019a). The report reviewed readily available internet data and found 22 example projects across the United States with some similarity to the OMF South project being developed at Midway Landfill. Most of the readily available data were limited in general to project overviews and status summaries of the redevelopment efforts. Specific details on regulatory challenges, permitting requirements, constructability considerations, and overarching health and safety concerns (both during construction and after redevelopment) were limited. Many of the redeveloped sites reviewed were relatively new, and long-term redevelopment-related studies (e.g., settlement issues, contamination migration, worker health and safety impacts, etc.) were not readily available.

The list was reduced to 16 representative developments, as shown in Table 2-1, more closely matching the Midway Landfill site, specifically on a closed landfill or former Superfund site.

TABLE 2-1

Other Landfill/Contaminated Site Redevelopments

Site Description	Location	Redevelopment
Munisport Landfill Superfund Site	North Miami, Florida	Two 25-story towers of luxury condominiums and several commercial businesses
Ringwood Mines/Landfill Superfund Site	Ringwood, New Jersey	Businesses, an industrial refuse disposal area, a municipal recycling center, the Ringwood Borough garage, a state park, and 50 private homes
Conrail Rail Yard Superfund Site	Elkhart, Indiana	Rail yard and associated maintenance facilities
Operating Industries, Inc. Landfill Superfund Site	Monterey Park, California	Commercial and retail operations
PJP Landfill Superfund Site	Jersey City, New Jersey	Prologis distribution center and structural supports for the Pulaski Skyway
Syosset Landfill Superfund Site	Oyster Bay, New York	Salt storage, storage, parking, sanitation vehicle refueling facility
Rossman Landfill	Oregon City, Oregon	Golf course, Discount Tire Store, and Home Depot (additional commercial development in the planning stages)
Cobb's Quarry Landfill	Beaverton, Oregon	Single- and multi-family homes
Northwest 58th Street Landfill Superfund Site	Hialeah, Florida	Numerous municipal-related office and operational facilities
Ogden Railroad Yard Superfund Site	Ogden, Utah	Museums, art galleries, shops, restaurants, and commuter rail line infrastructure
Western Pacific Railyard Superfund Site	Oroville, Washington	Maintenance shop, active rail line, and public drinking water well
Kentwood Landfill Superfund Site	Kentwood, Michigan	Two-story, 46,000 square foot public library facility
Santa Clara Landfill	Santa Clara, California	240-acre mixed use complex (commercial and residential)
Contaminated Site	St. Paul, Minnesota	Green Line Light Rail Transit OMF
Contaminated Site	St. Paul, Minnesota	Southwest Light Rail Transit Rail Support Facility
South Park Landfill	Seattle, Washington	Seattle South Transfer Station

Sound Transit contacted the facility owners to collect information related to their past landfill redevelopment experience. Seven of the redevelopments responded and were interviewed about their contaminated site redevelopment experience to obtain additional points of reference to better understand the advantages and disadvantages of reusing a landfill site. Sound Transit was also interested in better understanding possible long-term health impacts tied to reusing the former landfill sites and whether any special studies were required during the planning and permitting of landfill site redevelopment.

The information collected demonstrated that numerous landfill/contaminated sites have been successfully redeveloped. Several sites have also been redeveloped to support transportation infrastructure expansion, including projects where light rail and other transit infrastructure was installed. However, none of the site redevelopments significantly reflected the combined Midway Landfill site characteristics and the operational requirements of the OMF South project. For example, a rail facility developed on a stable, but contaminated, site will not require the same settlement considerations as if developed on a landfill.

There was general consensus from respondents regarding certain aspects of landfill site reuse, specifically that permitting processes were longer than for typical site development, given the requirements for coordination, review, and approval of contaminated site reuse.

None of the respondents reported knowledge of any human health-related concerns from working at or living within the redevelopment communities.

In addition to the OMFS Landfill Evaluation Report (Sound Transit 2019a), three other facility redevelopments were researched: a transit park-and-ride at McCollum Park in Snohomish County, Washington, a bus operations and maintenance facility in Memphis, Tennessee, and a mixed-use commercial/residential development in Everett, Washington.

The park-and-ride lot was of interest because it was locally known for settlement issues. In researching the site, the lot was constructed on the Emander Landfill. The landfill stopped receiving waste in 1967, and the waste mass was approximately 20 feet deep. Information was not readily available online as to any design and construction mitigation being performed at the site prior to lot construction. The site was not considered relevant to the OMF South project beyond emphasizing that settlement is expected to occur at former landfill sites.

The bus operations and maintenance facility is owned by the Memphis Area Transit Authority (MATA) and constructed on the Bellevue Landfill, with waste material 20 to 30 feet thick. Landfilling stopped in 1977, followed by facility construction in 1979. The site has experienced ongoing settlement requiring significant facility improvements to keep the facility operational. The buildings were constructed on piles, which has created large differential settlement at the building interfaces with the remaining unmitigated site infrastructure (i.e. the buildings have remained at the general installed elevation and the rest of the site has settled and pulled away from the buildings). LFG generation has also been an issue at the facility with ignitions and explosions during construction. Neither settlement nor LFG were properly mitigated during facility design and construction. No site-wide stabilization measures were instituted, and only LFG sensors and fans were installed in the buildings to account for methane generation. This site is relevant to the OMF South project as an example of the importance of engineered mitigation measures that are required for successful construction on landfills.

The mixed-use commercial/residential development is at the Everett Landfill and includes two adjacent properties. The project is in the planning stages and is expected to include construction of up to 900,000 square feet of mixed commercial use; 200,000 square feet of hotel space; and up to 1,400 residential units. The plan was approved by the Everett City Council on May 1, 2019.

The project will need to address ground settlement, human health and safety, regulatory, and legal risks similarly identified for the OMF South project if constructed at Midway Landfill. The current planned subsurface construction approach for the site is a temporary surcharge placed over the refuse area to further consolidate the material and reduce future settlement. Buildings will be constructed on piles. Construction requirements are expected to include:

- Environmental controls and health and safety requirements to be implemented during excavation including stormwater management, dust and odor control and waste handling;
- Landfill cap requirements that prevent infiltration into contained waste and prevent direct contact with waste;
- Installation and maintenance of an active LFG collection system below the cap that prevents LFG from entering enclosed spaces where it can be an explosive risk;
- Pile foundation requirements that protect underlying groundwater from migration of landfill leachate;
- Operational requirements for the existing leachate collection system to prevent leachate from entering the river; and
- Surface water management requirements to prevent infiltration into underlying waste and to prevent erosion of the surface materials.

The Everett Landfill redevelopment has not been completed but continues to advance. If Midway Landfill is selected as the preferred site for the OMF South, the Everett Landfill project could provide further information on the process and mitigation that will be required for landfill redevelopment.

2.4 Human Health Risk Assessment

A Midway Landfill Human Health Risk Assessment (HHRA) (Sound Transit 2020c) was performed for the OMF South project. The HHRA evaluated potential chronic health risks to Sound Transit personnel who work at the future site should it be selected for OMF South and waste be maintained on site. Non-toxicological hazards, including acute, physical risks associated with constructing and operating OMF South over a waste mass, were also discussed.

At the time of the HHRA, five landfill subsurface construction design options were being considered. In order to streamline the exposure assessment step of the HHRA and the non-toxicological hazards evaluation, the five subgrade construction design options were grouped into three future development concepts for OMF South based on the potential exposures associated with each construction design option. Human health risks were evaluated for the development concept that represents the worst-case exposures scenario based on current site conditions and potentially complete routes of exposure. The three concepts are described as follows.

Concept 1: OMF South built on an elevated structural platform. This concept includes an elevated platform constructed on shafts or pilings that are installed through the landfill cap and the underlying waste material. The landfill cap will be restored at penetrations and the gas system and other environmental controls will be preserved. This concept represents the High Platform option.

Concept 2: OMF South built on a slab on the surface of the landfill following full excavation and removal of underlying landfill waste. This concept includes removal of the landfill cap and underlying solid waste, screening and reuse of contaminated, but competent, soils contained in the landfill as fill, reconstruction of the landfill cap, reconstruction of environmental controls, and construction of a slab foundation. This concept represents the Full Excavation option.

Concept 3: This concept is a combination of Concepts 1 and 2 and will include removal of the landfill cap, partial removal of underlying solid waste, screening and reuse of contaminated, but competent, soils contained in the excavated portion of the landfill as fill, reconstruction of the landfill cap, reconstruction of environmental controls, and construction of the OMF South on a combination of slab foundation and an elevated platform on shafts or pilings. This concept represents the Low Platform, Hybrid 1, and Hybrid 2 options.

Based on evaluation of the historic available site data and supporting documents, the groundwater and LFG methane datasets were determined to be of sufficient quality and reliability for use in this risk assessment. However, based on the data evaluation for this HHRA, it was determined that the LFG data for volatile organic compounds (VOCs) and toxic inorganic gases were not representative of current, or future, site conditions, as they were collected more than 25 years ago from the LFG extraction system and, thus, do not accurately represent concentrations of volatile gases to which future workers may be exposed. In addition, data collected from the LFG extraction system do not provide an appropriate measure of the concentrations that workers may be exposed to at OMF South. Below is the summary of findings from the HHRA. The HHRA should be reviewed in its entirety for a complete understanding of the exposure and toxicological assessments and non-toxicological hazards evaluation. Due to the lack of recent LFG VOC data, an April 2020 sampling event was performed as discussed below.

The HHRA found that occupational exposures to VOCs in groundwater and to methane in LFG are not expected to result in adverse chronic health effects for any OMF South worker.

However, the potential risk of adverse chronic health effects associated with occupational exposures to contaminants of interest (COIs) in LFG could not be characterized due to a lack of representative data. In order to quantify occupational risk at OMF South, post-construction sampling of VOCs and toxic inorganic gases is needed (e.g., sub-slab soil gas and/or indoor air sampling) to provide an appropriate measure of the concentrations that workers may be exposed to at OMF South. Appropriate engineered protections for occupational exposures will need to be developed based on the final selected OMF South subsurface construction design option.

The non-toxicological hazards (methane explosion risk, seismic considerations, and hazards associated with construction activities) evaluated for the Midway Landfill can largely be managed through appropriate engineered protections, health and safety protocols, construction design standards, and site control and environmental protection plans. Risk management approaches for non-toxicological hazards will need to be developed based on the final selected OMF South subsurface construction design option.

Subsequent to the HHRA development, a limited, one round of select LFG sampling was performed in April 2020. The sampling and results were discussed in a Midway Landfill Human Health Risk Assessment Addendum (Sound Transit 2020d) to the HHRA and are summarized below.

The LFG analysis included samples collected directly from the LFG extraction system: one combined sample from the manifold to the flare inlet and eight from individual LFG extraction wells. In addition, two opportunistic air grab samples were collected in areas where the landfill cap had been breached during a geotechnical investigation. The intent of the LFG investigation was to provide Sound Transit with information about the types and concentrations of VOCs and inorganic gases found in LFG at the Midway Landfill under current site conditions.

Data limitations that impact the interpretation and application of these data in site characterization and risk assessment were identified during the data evaluation process. These limitations include a relatively small number of LFG sample locations within a large area (>60 acres), potential selection bias, temporal limitations associated with a one-time sampling event, limited understanding of the underlying waste type and conditions and applied vacuum pressure and resulting radius of influence for sampled wells, and limitations of using VOC concentrations found in the LFG extraction system to quantify occupation exposures and risk at OMF South.

The April 2020 LFG extraction system sample results indicate that several VOCs remain in LFG at the site; however, the VOCs with the highest concentrations in 2020 (benzene, ethylbenzene, and hydrogen sulfide) have decreased substantially since 1988, but continue to exceed one or more regulatory screening level.

VOC results from the manifold and extraction wells and from co-located wells demonstrate that concentrations can vary significantly by depth and by location throughout the landfill footprint. The sampled extraction wells with the highest concentrations of benzene, ethylbenzene, and hydrogen sulfide include those north of the planned OMF South main building (GW-42S and GW-42D) and within the east side of the planned OMF South main building (GW-48S and GW-48D).

The April 2020 LFG sampling event did not provide any new information that would result in a change in the current conceptual site model. The primary source of contaminants of potential concern (COPCs) at the site, chemical release mechanisms and environmental transport processes, and potentially complete routes of exposure for specific occupations at OMF South remain the same as those presented in the HHRA.

As discussed above and in the HHRA, samples collected directly from the LFG extraction system are not representative of VOC concentrations in subsurface gas that could pose an unacceptable risk to indoor air quality. The LFG extraction system samples should not be used to quantify occupational exposures and resulting risk. As a result, the April 2020 pre-construction sampling results were not used to identify subsurface soil gas COPCs.

However, because hydrogen sulfide was detected at relatively high concentrations in LFG samples during the April 2020 sampling event, a toxicity profile for hydrogen sulfide is included in the HHRA Addendum. Overall, the HHRA findings and conclusions have not changed by inclusion of the Midway Landfill Human Health Risk Assessment Addendum.

As stated in the HHRA findings, the migration of LFG through the subsurface to indoor and ambient air is currently controlled by the LFG extraction system and the landfill cap. Continued operation and maintenance of all components of the remedy is required if any portion of the property is sold, leased, transferred, or otherwise conveyed. As a result, it is expected that future development of OMF South at the Midway Landfill, if refuse remains, would include an LFG system and landfill cap and other engineered protections to mitigate and monitor vapor intrusion of LFG (including methane) to indoor air.

2.5 Landfill Site Engineering and Optimization

In Phase 1 of siting OMF South, high-level redevelopment concepts for the Midway Landfill Alternative were generated. As the Midway Landfill Alternative was advanced to Phase 2 in the evaluation process, additional engineering and site optimization was performed to more realistically evaluate the alternative. This effort is captured in the Midway Landfill Site Engineering Optimization Report (Sound Transit 2019b) and the Conceptual Basis of Design Report (Sound Transit 2020a).

The Midway Landfill Site Engineering Optimization Report summarized the development of a preferred site layout and five potential subsurface construction design options. The landfill design optimization included two workshops focused on ground-settlement solutions.

The first workshop introduced the Phase 1 Midway Landfill Alternative OMF South concepts and Sound Transit's operational and maintenance criteria (Sound Transit 2018) for the facility to a broad stakeholder group which included representatives from Sound Transit, SPU, City of Seattle, City of Kent, City of Federal Way, WSDOT, and various consultants . Based on this information, the workshop developed a range of concepts that could potentially improve the Phase 1 designs and mitigate settlement risk.

Sound Transit advanced OMF South design options based on the first workshop and presented the results to the same group of stakeholders in a second workshop. The second workshop reviewed the first workshop proposed settlement solutions and Sound Transit's evaluation process. Sound Transit presented initial Phase 2 design concepts for further discussion.

At the conclusion of the second workshop, the cross sections for the initial design concepts were modified resulting in the following five potential subsurface construction design options.

- High Platform – High Structural Platform with No Excavation
- Low Platform – Low Structural Platform with Some Excavation
- Hybrid 1 – Excavation with Ground Improvements (Buildings on Drilled Shafts)
- Hybrid 2 – Excavation with Ground Improvements (Slab on Grade for Tracks and Buildings on Drilled Shaft)
- Full Excavation – Full Excavation and Backfill with Competent Soils

The five options would generally share the same horizontal OMF South layout. The design options were further refined through the 10% design process, as discussed in the Conceptual Basis of Design Report (Sound Transit 2020a) and the landfill preparation assessment captured in the Interim Midway Landfill Preparation Memorandum (Sound Transit 2020b). The assessment of Alternatives Evaluation Matrix developed for the Interim Midway Landfill Preparation Memorandum resulted in the five options being reduced to three options that address a reasonable and broad range of options for further study, which are discussed in Section 2.6.

The 10% design process primarily advanced the OMF South site layout and optimum site grading to connect to FWLE mainline as well as track design for lead tracks for all three design options. The structural design of shafts and slabs was advanced based on updated design loads, design criteria on settlement, and geotechnical data. Additional geotechnical data were also used to determine the maximum depth of landfill material to remain in place and be deep dynamic compacted to meet settlement criteria for the Hybrid 2 option. The original geotechnical data were supported by additional geotechnical investigations as detailed in the OMFS Preliminary Geotechnical Recommendations (Sound Transit 2020e).

2.6 Landfill Preparation Requirements

The Interim Midway Landfill Preparation Memorandum (Sound Transit 2020b) was prepared to assess the landfill preparations required to implement the five potential subsurface construction design options at Midway Landfill that were developed during the landfill optimization process.

Since the development of the Interim Midway Landfill Preparation Memorandum, geotechnical technical investigations have been performed at Midway Landfill to further define evaluation assumptions, the design has been advanced to approximately 10% design, and a landfill preparation constructability review was conducted. The geotechnical investigation and 10% design efforts are documented in the OMFS Preliminary Geotechnical Recommendations (Sound Transit 2020e) and Conceptual Basis of Design Report (Sound Transit 2020a), respectively.

This section generally follows the organization of the Interim Midway Landfill Preparation Memorandum, with the exception of the original five potential subsurface construction design options being reduced to three. The current three potential subsurface construction design options being considered include:

- Low Platform – Low Structural Platform with Some Excavation
- Hybrid 2 – Excavation with Ground Improvements (Slab on Grade for Tracks and Buildings on Drilled Shaft)
- Full Excavation – Full Excavation and Backfill with Competent Soils

The High Platform – High Structural Platform with No Excavation was eliminated in preference of the Low Platform option based on the Low Platform elevation compatibility for the connection to the FWLE main line. The Hybrid 1 – Excavation with Ground Improvements (Buildings on Drilled Shafts) was eliminated due to similarities to Hybrid 2 and a preference for the Hybrid 2 slab on grade for the tracks.

2.6.1 Three Landfill Subsurface Construction Design Options

Each of the three OMF South subsurface construction design options at Midway Landfill generally has the same horizontal layout and surface features as shown in Figure 1-2. The three options primarily vary in subgrade and foundation concepts. The three options are shown in Figures 2-1 through 2-3. The options are consistent with those described in the Conceptual Basis of Design Report. The report should be reviewed for more detail pertaining to the OMF South project and the design of each construction option.

2.6.2 Construction Evaluation

The construction evaluation is a high-level discussion of landfill subsurface construction design options pertaining to the Midway Landfill Alternative for the OMF South Draft Environmental Impact Statement. The discussion is based on operations and maintenance requirements, available information, and reasonable assumptions intended to develop a planning-level comparison among the three design options. If the Midway Landfill Alternative advances, assumptions will be further refined to create a more detailed assessment of landfill preparation requirements.

The discussion presents possible subsurface construction approaches for the three design options to develop planning-level estimates of earthwork and structural requirements and inform the traffic analysis. Assumptions and influencing factors may vary depending on construction contractor means and methods and regulatory requirements.

2.6.2.1 Earthwork Process

Materials anticipated to be encountered during landfill excavation include clean cover soil, landfill cap geosynthetic materials, and refuse material. Clean cover soil can be temporarily stored on site for reuse during OMF South construction. Landfill cap geosynthetics and refuse material excavated will require one of the following:

1. Export and disposal off site,
2. Relocation on site, or
3. On-site material screening to retain competent soils for reuse on site and export of deleterious materials for disposal off site.

According to the OMFS Preliminary Geotechnical Recommendations (Sound Transit 2020e), the average unit weight within the refuse ranged from 50 to 90 pounds per cubic foot (lb/cf), or 1.01 tons per cubic yard (ton/cy). For calculation purposes, the evaluation used an average in-place unit weight of refuse of 75 lb/cf. The loosening of material during the excavation process is assumed to result in a lower average material density; however, it is assumed that 30 tons of export material per container will be achievable, equivalent to a loose density of 51.5 lb/cf, or 0.7 ton/cy. The recommendations also concluded that a typical soil column at the Midway landfill could be composed of between 50 and 70 percent waste, which would correspond to between 30 and 50 percent soil that could be considered for reuse. For calculation purposes, the evaluation used an average excavated material screening reuse of 40 percent, with the remaining 60 percent of material exported for disposal.

The reusable material will be contaminated and require environmental controls during handling to avoid contamination of clean material and surface water. The reuse of the material will require oversight by a geotechnical engineer to ensure proper mixing and placement for acceptable soil stability. During placement, some initially classified reuse material may be deemed unsuitable and require disposal off site.

The Low Platform option reuses excavated material without screening. This approach is intended to balance cut and fill quantities and reduce export requirements. Drilling tailings are assumed to require export. The reused material is not required to be structurally competent, since the Low Platform option relies on drilled shafts for support.

Even though there is a quantity of clean cover material on the site, the amount is unknown. Based on the high-level nature of this evaluation and the proportionately larger quantity of refuse material, the entire excavation quantity calculated and shown on Figures 2-1 through 2-3 is assumed to be refuse. A quantity of clean cover material has not been distinguished from the bulk quantities.

Active excavation and hauling are assumed to be 12 hours per day (hr/day), 6 days per week (day/wk). The actual workday may be 16 hours with two shifts. Due to general inefficiencies, breaks, fueling and maintenance, irregularities at the start and finish of shifts, and other potential operational impacts, 12 hours of active hauling was assumed to be the average.

Excavation into refuse is assumed to be permitted only between May 1 and September 30, which excludes wet season construction. This results in a construction season of approximately 22 weeks each year. The construction season is assumed to be limited to reduce the amount of precipitation that may contact refuse and become contaminated water that could potentially infiltrate into the open area of the landfill, further contributing to contaminated groundwater that exists at the site. It is assumed that regulatory agencies will prohibit or restrict open landfill excavation during the wet season to protect against groundwater contamination. Shaft installation and other work could be performed during the wet season provided the work area maintains environmental protections.

Due to the irregular nature of the material typically found within a landfill, there will be the potential to encounter unexpected subsurface conditions during the excavation process. It is assumed that the construction contractor will be required to have resources available to manage irregular materials encountered during bulk excavation and redirect the work effort without delays to the project timeline. The large available work area of the total site work area supports the reasonableness of this assumption.

2.6.2.2 Drilled Shaft and Slab Installation

The landfill preparation includes two preliminary structural options; the Low Platform and Hybrid 2 options. These two subsurface construction design options include drilled shaft and slab elements, as discussed in Section 2.5.

The Low Platform option consists of precast, prestressed void slabs supported on approximately 700 drilled shafts. The drilled shafts are 10 feet in diameter, distributed on a 35-foot by 70-foot grid under the buildings, track, and drainage vault area as shown in Figure 2-4.

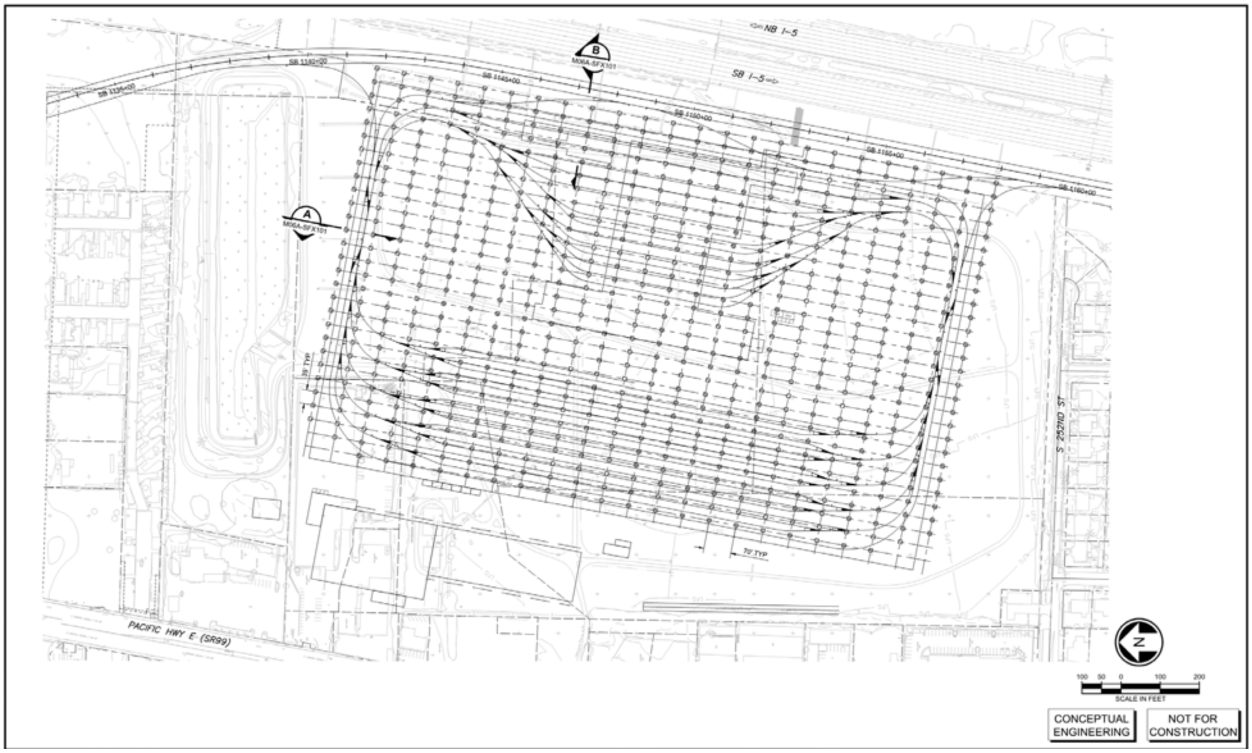

Figure 2-4. Low Platform Shaft Layout

The shafts are enclosed in steel casings due to the composition of the landfill material, as evaluated from the geotechnical boring samples performed for the OMFS Preliminary Geotechnical Recommendations (Sound Transit 2020e). The grid spacing has changed from the previous 100-foot by 100-foot grid assumed during the landfill optimization process. The refined spacing was a result of advancing the OMF South design estimates for facility loads and landfill characteristics. The slab on top of the shaft was designed using WSDOT standard precast prestressed void slabs, with approximate 6-inch-thick cast-in-place concrete on top of the void slabs, to optimize the design as well as to accommodate underground utilities and drainage. The change in shaft and slab quantity is a result of design progression.

Shaft installation generally consists of excavation, placing a reinforcement cage, and pouring concrete that is embedded through the landfill and into native, competent material. Average shaft lengths range between approximate 130 feet and 180 feet from finished grade depending on the location within the landfill and associated depth to competent material. It is assumed each shaft will require 4 days for installation.

The Hybrid 2 option consists of the same shaft and slab design below buildings (approximately 105 shafts) as the Low Platform option and a cast-in-place reinforced concrete waffle plate slab structure for the track area. The Hybrid 2 shaft layout is shown in Figure 2-5. The top slab in the track yard is 1 foot thick with webs below the slab. The cross section of each web is 18 inches wide and 30 inches tall. Slab and shaft concepts are shown in Figure 2-6. The waffle plate slab structure is casted directly on the compacted soil foundation without shafts and supports the entire operation and maintenance yard, except the buildings are supported on shaft foundations.

Figure 2-6. Slab and Shaft Concepts

Shaft and slab installation are assumed to occur in coordination with the earthwork process, with similar material hauling hours and work season. The work will be phased in with the earthwork, with shafts installed in exposed refuse areas prior to landfill cap installation and clean backfill. Shafts through refuse will need to be booted (watertight and airtight connection of the landfill cap geomembrane to the shaft) through the replacement landfill cap to create a sealed system. Slab installation should be permitted to occur during the wet season, since this work will be performed in a completed landfill capped area without exposed refuse. Drilled shaft installation may be permitted during the wet season based on a small and controllable work area pertaining to the individual shafts.

Refuse exhumed during drilling has been included in the earthwork quantities. The drilling process is assumed to be prohibitive to material screening and reuse of the exhumed material, requiring export for disposal. Concrete import is accounted for as an import quantity associated with the shafts and slabs.

Though Hybrid 2 includes drilled shafts under the building, these shafts would likely be removed from the design in favor of localized over excavation to competent soils below the building. The Midway Landfill Site Engineering Optimization Report (Sound Transit 2019b) assumed that a 40-foot thickness of refuse could remain in-place with deep dynamic compaction while still achieving the settlement tolerance required for the OMF South. The recent OMFS Preliminary Geotechnical Recommendations (Sound Transit 2020e) indicates that the thickness of refuse left in-place would need to be a maximum of 6 feet, as shown in Figure 2-2, still requiring deep dynamic compaction. The smaller quantity of refuse likely warrants its removal rather than the installation of full-length drilled shafts. Removing the refuse will reduce project costs and avoid introducing shaft installation activities to the construction. Leaving the 6 feet of refuse in place with deep dynamic compaction is also not an option below buildings due to the more stringent settlement criteria.

2.6.2.3 Environment Considerations during Construction

As stated above, wet season construction is assumed to be prohibited during landfill preparation due to the greater potential to generate contaminated groundwater through penetrations through the existing landfill cap. This restriction results in a May 1 to September 30 work window each year for contaminated earthwork activities. Other earthwork activities performed within the wet season, if conducted, would likely result in low productivity and efficiencies due to limitations in the workability of the material and inclement weather shutdowns.

In general, the exposed refuse area of the work site is assumed to be limited to 5 acres in size. A specific allowable exposed refuse area size has yet to be established with the regulators. The 5-acre area was assumed as a reasonable size to perform work while managing environmental protection and preservation of the landfill environmental controls. It is assumed that a construction contractor will be able to secure (cover refuse and manage stormwater) a 5-acre exposed area at the end of each day and in anticipation of inclement weather. The construction contractor will also need to control dust on dry and windy days. Precipitation and surface water run-on will need to be managed in the exposed refuse area to avoid water contamination and infiltration into the landfill that could result in further contamination of groundwater. Water collected within the open refuse area will need to be hauled off site and disposed of as wastewater. It is assumed that some inclement weather will occur during dry season construction, which will increase the schedule duration by 5 percent.

It is also assumed that a 5-acre open refuse area can be managed without negatively impacting the active LFG system at the landfill. The LFG collection and conveyance system will be required to remain active during construction to prevent off-site migration of LFG. During the construction, the LFG system will need to be continuously reconfigured to maintain effectiveness. Portions of the system will need to be demolished and replaced as the work progresses through the site. Additionally, the system will need to be managed to prevent air intrusion from the open refuse area that could contribute to a landfill fire.

The application of a 5-acre open refuse area limitation will be more manageable for the Low Platform option based on the maximum refuse excavation and fill depth of approximately 15 feet, allowing that option to utilize the entire 5-arce area for work activities. The Hybrid 2 and Full Excavation options have significant excavation depth requirements of up to and in excess of 110 feet. If the horizontal footprint of the open refuse area is limited to 5 acres, the available work area within the excavation, or excavation floor, will be reduced in size based on depth and the space consumed by the side slopes required for a stable excavation. Side slopes are assumed to range from 1:1 (horizontal to vertical) to 2:1. To maintain an effective work area size for these two options, it is likely that the excavation within thick refuse will need to progress in lifts (i.e., 30 feet deep), progressively excavating the entire landfill surface down one lift at a time. Excavation in lifts would still require the 5-acre open refuse area limitation, which could be achieved through the installation of a temporary landfill cap phased behind the progressing lift excavation.

If material screening will take place for on-site reuse of contaminated, competent backfill material, 5 acres may not be an adequate exposed refuse work area to accommodate continuous excavation, vehicle loading, screening, stockpiling, and backfill of material. The depth of excavation and layback of slopes will also factor into area requirements. It may be possible to use a non-open refuse area on the site for material processing and handling; however, the area would have to be set up to manage the contamination and protect clean areas.

If more than 5 acres of open refuse area is allowed, concurrent construction activities will have more available space; however, work progression may not directly result in a decrease in schedule requirements. If the rate of onsite excavation can increase, available trucking and road capacity and the capacity of the export receiving facility may then become limiting factors, as discussed in Sections 2.6.2.4 and 2.6.3.

Note that reuse of the screened material on site will be subject to regulatory approval. Environmental regulators may require any exhumed refuse to be disposed of at a permitted facility meeting current standards without the option to reuse on site. The FWLE project has been allowed to reuse refuse material on site; however, the quality of that material is better understood, and the scale of that work is significantly smaller than that proposed for OMF South.

The hauling of contaminated material will be in fully enclosed intermodal containers. If material is determined to be hazardous, hauling requirements will need to be verified based on the material.

Vehicles and equipment driving through a contaminated area will likely need to cross a wheel wash as they exit the area to clean the tires and avoid tracking contaminated material elsewhere on site and off site.

Each of the three options will result in refuse retained on site, which will require the preservation, or reinstallation, of a permanent landfill cap system, LFG system, and groundwater monitoring system. The Full Excavation approach may be able to remove

LFG-generating material through screening; however, contaminated soil may still result in contaminated soil vapor that will need management.

2.6.2.4 Disposal Considerations

Excavated material exported from the landfill will require disposal at a regulated facility, assumed to be a Subtitle D landfill in accordance with the Resource Conservation and Recovery Act (RCRA). The material testing performed during the development of the OMFS Preliminary Geotechnical Recommendations (Sound Transit 2020e) indicated that the primary contaminants in the refuse material sampled are petroleum hydrocarbons and that, in general, there were no chemicals present at concentrations posing significant exposure threats. However, there were some chemical concentrations that slightly exceeded MTCA Method A levels. The age of the landfill, and possible less stringent acceptance criteria, presents a risk that there will be material quantities classified as hazardous requiring disposal at a more expensive Subtitle C landfill; however, since the facility was operated as an MSW landfill, it is assumed that the majority of material encountered will be accepted at a currently permitted MSW Subtitle D landfill.

Within the Pacific Northwest, it is expected that three solid waste firms have the available landfill capacity for the disposal of the material quantities required, specifically for the Hybrid 2 and Full Excavation options. Export disposal quantities are discussed in Section 2.6.2.7. With material reuse on site, the Hybrid 2 and Full Excavation options will require 2.6 million and 3 million tons of disposal export, respectively.

The firms are Republic Services, Waste Management, and Waste Connections. The three firms each operate a regional Subtitle D landfill that is accessible by rail. Table 2-2 is based on the King County 2019 Comprehensive Solid Waste Management Plan (King County Solid Waste Division 2019) and provides information on each landfill.

TABLE 2-2
Regional Disposal Capacity

Landfill	Location	Owner	Permitted Capacity (tons)	Remaining Capacity (tons, 2016)
Roosevelt Regional Landfill	Klickitat County, WA	Republic Services	244,600,000	120,000,000
Columbia Ridge Landfill and Recycling Center	Gilliam County, OR	Waste Management	345,275,000	329,000,000
Finley Buttes Regional Landfill	Morrow County, OR	Waste Connections	158,9000,000	131,000,000

The travel distance to these landfills warrants container shipment by rail. Trucks leaving the Midway Landfill will need to go to an intermodal facility for container offload onto trains. At the facility, the trucks will be reloaded with empty containers.

A number of intermodal facilities exist in the Seattle area that are owned by either a solid waste firm or a railroad. The two primary railroads are Burlington Northern Santa Fe Railroad (BNSF) and Union Pacific Railroad (UP).

Based on the hauling scenario discussed in Section 2.6.2.6, the intermodal facility is expected to handle an export truck arriving every 2.5 minutes on average. It is assumed that one or multiple existing intermodal facilities in South Seattle will be able to accommodate the exported quantities from the Midway Landfill. This may or may not be possible for the Hybrid 2 and Full Excavation options considering the large quantity and schedule requirements, and a project-specific intermodal facility may be required or, at a minimum, an existing facility may require expansion. It is also assumed that the rail service provider can meet the train capacity requirements.

Based on an intermodal facility located in Seattle, the travel distance will be 20 miles one way, requiring an assumed 40 minutes each direction. The queue, unload, and load time required at the intermodal facility is assumed to be 10 minutes.

Weighing of containers is assumed to occur at the intermodal facility or disposal landfill.

It is expected that the export disposal will be contracted through the construction contractor, with the solid waste firm as a subcontractor. The railroad component is expected to be a second-tier subcontractor through the solid waste firm. Due to the complexity of the solid waste handling and disposal component of the project, including the potential intermodal facility construct aspect, the bidding for this service under all the options is expected to require at least 6 months.

2.6.2.5 Construction Phasing and Material Reuse

As discussed in Section 2.6.2.3, construction phasing will be required to maintain the environmental controls at the landfill. A limited portion of the landfill will be allowed to be exposed at one time. Within this exposed refuse area, a number of activities are expected to occur simultaneously, depending on the construction approach, with each activity in sequence after the preceding activity and the preceding activity moving on to the next area. The exposed refuse area would be able to advance once the landfill cap, temporary or permanent, is reinstalled in the previous work area. Activities may include different combinations of the following.

1. Disassembly/removal and temporary reinstallation of the LFG system
2. Removal of the landfill cap system
3. Excavation of refuse material
4. Screening of refuse material
5. Export of screened unsuitable material

6. Dynamic compaction of the subgrade (if applicable)
7. Mixing, placement, and compaction of screened competent reuse material
8. Drilled shaft installation (if applicable)
9. Import and installation of competent material
10. Installation of permanent landfill cap system and LFG system
11. Slab installation (if applicable)

The assumed 5-acre open refuse area will be very limiting for the space demands and to maintain efficiencies. Phasing will be further complicated with greater excavation depth requirements and the space consumption from layback slopes. There may be some relief if the area can be increased and truck load-out and screening can be performed outside the open refuse area; however, this will create additional contamination areas to manage.

The phased nature of the work allows the construction contractor to be able to respond to changed conditions by moving to another portion of the site, as needed, without greatly impacting schedule. This also provides the opportunity to effectively plan and execute preparatory and sequential work.

Also, the landfill preparation work can be performed concurrently with portions of the OMF South building and track construction. The OMF South building and track construction can begin in areas that have achieved final grade or completion of the slab work. Phasing of OMF South construction will be dependent on the excavation and backfill approach (i.e., excavation in lifts). While it’s too early in the project to get into detailed construction phase planning, those plans will be required by regulatory agencies prior to approval of ground disturbing work.

2.6.2.6 Truck Trips – Export and Import

Disposal Export

Excavated material for export off site is assumed to be loaded into 20-foot intermodal containers on waiting trucks. The intermodal containers will be limited to a capacity of 30 tons due to roadway load restrictions set by local agencies and WSDOT. The containers will be transported off site for direct load onto railcars at an intermodal facility.

The 5-acre open refuse area is assumed to be able to accommodate four active truck load-out locations, with an on-site load time of 10 minutes each. The number of load-out stations will depend on construction contractor means and methods to perform the work. Four stations were assumed as a possible number based on space limitations and competing work activities.

Based on the discussion of intermodal facilities, total round-trip time for a truck will be 100 minutes. Each load station at the Midway Landfill will be able to accommodate up to 10 circulating trucks, for a total of 40 export trucks operating during peak time.

Based on a 12-hour workday, each truck is assumed to make seven trips per day. At 40 operating trucks, this equates to 280 truck trips per day. This is an approximate value that does not account for irregularity at the beginning and end of the day.

Disposal export quantity estimates are shown in Table 2-3 in Section 2.6.2.7.

Soil Import

Importing soil for backfill will need to be performed separately from the export operation for excavated refuse. There is not expected to be an opportunity to gain efficiency from export trucks returning to the site with imported soil. The export trucks will use intermodal containers. The intermodal containers are used for transfer to and from the trains and are not suited for dumping import soil on site if the containers were loaded with clean import soil on the return trip. Import trucks will need to be dump trucks with trailers with an assumed capacity of 20 cy. Import material is assumed to arrive in a loose density equivalent to 130 percent of the volume of in-place fill.

The total round-trip time for import trucks is assumed to be 100 minutes. This assumption is based on a hypothetical material supply location in Maple Valley, Washington. When on site, trucks will dump either in the fill area or at a stockpile location.

The demand for import material will be reduced based on assumptions pertaining to excavation screening and reusable material and a lower final site elevation than the existing condition. The total amount of import trucks is assumed to be equally distributed throughout the export duration.

Soil import quantity estimates are shown in Table 2-3 in Section 2.6.2.7.

Concrete Import

Concrete import for shafts and slabs is assumed to arrive in 9 cy truckloads. The import is assumed to be equally distributed throughout the shaft and slab installation period. Concrete will be locally sourced from an unknown location and is expected to be imported following the same site-access requirements as other import and export operations.

Concrete import quantity estimates are shown in Table 2-3 in Section 2.6.2.7.

2.6.2.7 Results

The assumptions discussed above are summarized below.

Assumptions:

1. Average in-place refuse density is 75 lb/cf, or 1.01 ton/cy.
2. Average export density is 51.5 lb/cf, or 0.70 ton/cy, minimum.
3. 40 percent by volume reusable excavated material.
4. Average import soil density ratio is 1.3 in-place/loose.

5. Active excavation is 12 hr/day, 6 day/wk, 22 weeks per year (wk/yr).
6. Exposed refuse area is 5 acres.
7. Inclement weather will increase the project duration by 5 percent.
8. A 5-acre area can load four export trucks at a time.
9. Each export truck is on site for 10 minutes.
10. Export truck travel distance is 20 miles each way.
11. Export truck trip time each direction is 40 minutes.
12. Export truck time at the off-site facility is 10 minutes.
13. Total export truck trip time is 100 minutes per load.
14. Circulating export trucks operating per load area is 10.
15. Total export trucks operating is 40.
16. Export trips per day per truck is seven.
17. Export truck trips per day is 280.
18. Export truck capacity is 30 tons
19. Soil import truck capacity is 20 cy.
20. Concrete import truck capacity is 9 cy.

Applying these assumptions and the quantities developed during the 10% design to the three landfill subsurface construction design options results in the landfill preparation requirements summarized in Table 2-3 and Table 2-4.

TABLE 2-3
Landfill Preparation Material Requirements

Construction Design Option	In-Place Excavation (cy)	Excavation (ton)	Material Export (ton)	In-Place Fill (cy)	In-Place Reuse (cy)	In-Place Import (cy)	Concrete Import (cy)
Low Platform	1,010,000	1,023,000	678,000	340,000	340,000	0	531,000
Hybrid 2	4,270,000	4,323,000	2,592,000	2,890,000	1,710,000	1,180,000	165,000
Full Excavation	4,870,000	4,931,000	2,956,500	3,510,000	1,950,000	1,560,000	0

The in-place excavation volume was converted to excavation tonnage to be consistent with the industry approach to material export and disposal. In-place volume remains applicable to the assessment for import materials. The in-place reuse volume directly applies reuse at 40 percent of the in-place excavation volume and does not account for volume differences between screened reuse and export material.

TABLE 2-4
Landfill Preparation Daily Hauling Requirements

Construction Design Option	Export Truck Trips per Day	Soil Import Truck Trips per Day	Concrete Import Truck Trips per Day	Total Truck Trips per Day
Low Platform	20	0	51	71
Hybrid 2	280	237	47	564
Full Excavation	280	274	0	554

Concrete import truck trips are equally dispersed over the general schedule durations for shaft and slab installation. Export and soil import truck trips for the Low Platform option are also dispersed over the general schedule durations for shaft and slab installation. Export and soil import truck trips for the Hybrid 2 and Full Excavation options have been equally dispersed over the assumed landfill preparation period, dry season hauling only.

Truck trips include only bulk earthwork and concrete. Other vehicle trips (i.e., landfill closure system materials and concrete reinforcement) have not been evaluated. Complete construction traffic will be evaluated as part of the Draft Environmental Impact Statement.

2.6.3 Traffic Analysis

2.6.3.1 Truck Haul Routes

Access to and from the site for inbound and outbound trucks is assumed to be via right turns. No left turns into or out of the site are assumed. Left turns would increase the likelihood of on-site or off-site queueing of vehicles, causing congestion. Outbound trucks exiting the site would travel north on SR 99 and access I-5 via Kent-Des Moines Road (SR 516). Inbound trucks would travel on I-5, exiting at S 272nd Street. The inbound trucks would travel westbound on S 272nd Street to SR 99, where they would turn north and travel to the site. Excavation export is assumed to be to the north to reach an intermodal facility. Trucks importing material would follow the same routes in the vicinity of the site, although the origin for import concrete and soil material is unknown.

Assumed construction haul routes to the north are shown on Figure 2-4. Actual traffic routes will need to be established for the construction through coordination with the local jurisdiction permit process.

2.6.3.2 Level of Service Considerations

Trucks would traverse the haul routes during the entirety of the assumed 12-hour daily hauling period, including both directions during AM and PM peak. As described in Section 2.6.2.6, the maximum number of export trucks operating at the site is 40, each performing 7 round trips per day, for a total of 280 daily truck trips. With 280 truck trips during the daily construction period, the average number of truck trips per hour is 23-24. Trucks are assumed to be accessing the site at uniform intervals throughout the daily hauling period, with some potential for irregularity or bunching at the beginning and end of the day. Import trucks for the Hybrid 2 and Full Excavation options represent truck trips similar to the maximum assumed export truck trips. Given that the daily truck trip volume is estimated to increase by about 284 and 274 trips per day to facilitate importing material for the Hybrid 2 and Full Excavation options, respectively, it is estimated that 24 additional trucks would be operating at the site each hour, for a total of about 48 truck trips per hour. The Low Platform construction option includes import of concrete but would require fewer truck trips than the other two options. The Low Platform option would have a total of approximately 6 trucks per hour.

Given their size and slower operating speeds, trucks were assigned a passenger car equivalency (PCE) value of 2.5 for this evaluation. Additionally, each round trip includes an outbound and inbound segment, resulting in a total of 700 PCE daily trips in the study area associated with export activity (280 truck trips x 2.5 PCE) for the Hybrid 2 and Full Excavation options. Import activity for the Hybrid 2 option would be worst case and result in approximately 710 PCE daily trips in the study area (284 truck trips x 2.5 PCE).

To estimate traffic operation impacts, the truck trips are assumed to be distributed evenly throughout the day and are based on the ability of the yard and the receiving facility to process the trucks. These assumptions are outlined in Section 2.6 of this plan. The 2.5 PCE factor is applied to the truck volume to give planners information about the number of new trips that would need to be accommodated along the truck routes. Below, Table 2-5 outlines the number of peak hour trucks and associated PCEs for each construction scenario.

TABLE 2-5

Passenger Car Equivalency for Each Approach

Construction Design Option	Daily			Hourly			Hourly PCE		
	Export	Import	Total	Export	Import	Total	Export	Import	Total
Low Platform	20	51	71	2	5	7	5	13	18
Hybrid 2	280	284	564	24	24	48	60	60	120
Full Excavation	280	274	554	24	24	48	60	60	120

The PCEs shown in the table would be the same for exiting and entering the site during the peak hour. The highest-impact approach would be the Hybrid 2 and Full Excavation options, with 120 PCE.

As shown in Figures 2-5 and 2-6, Google Maps (January 2020) reports almost all sections of the haul routes operate at “good” or “fair” conditions during both peak periods (typical traffic on Wednesdays at 7 a.m. and 5 p.m. was used to represent the AM and PM peak periods, respectively). The exceptions are northbound SR 99 approaching Kent-Des Moines Road during the 8 a.m. time period and the eastbound segment of Kent-Des Moines Road at the northbound

I-5 on-ramp, which operate at “poor” conditions during the AM peak period, as does the I-5 mainline. If 120 additional PCE vehicles of either the Hybrid 2 or Full Excavation options join the backup congestion on the I-5 northbound ramp during peak hours, congestion on Kent-Des Moines Road and possibly SR 99 would likely occur. Some example strategies to reduce impacts to local traffic could include using multiple routes, limiting truck activity during the peak traffic hours, and changing the end point location to be south.

If one or more end point hauling locations can be to the south, traffic impacts could be reduced through provision of direct access to I-5 southbound from the site. A potential haul route may be able to be developed north of the existing stormwater pond, which would allow for site access under the elevated FWLE guideway and to I-5. Access would also be subject to WSDOT and FHWA approval.

Given the good or fair operating conditions for other segments of the haul routes, it is assumed that the additional 120 hourly PCE trips for each route would not result in significant degradation to the operating conditions in these areas.

Trucks would enter and exit the site via SR 99. When trucks exit the facility and merge into traffic on SR 99, they would operate at slower speeds due to heavy loads. Returning trucks would also slow down to make the turn into the facility, causing minor delays. In order to reduce potential impacts to mainline traffic on SR 99 at the access point, a short acceleration lane could be constructed to accommodate outbound trucks and a short deceleration lane could be constructed to accommodate inbound trucks.

Midway Landfill Alternative

OMF South

Internal document for the purposes of informing the design and construction approach for the Midway Landfill Alternative

2.6.4 Compatibility with the Known Status of FWLE Construction

If constructed at Midway Landfill, OMF South will connect to the mainline of the FWLE. The current FWLE mainline design is not at an elevation and grade to allow direct connections to the proposed OMF South lead tracks. The three OMF South Midway Landfill design options have been developed, with the yard at elevations 365 feet (Hybrid 2 and Full Excavation) and 380 feet (Low Platform). The FWLE will follow the general grade of I-5, while OMF South will be flat.

There are currently five proposed track connections between the FWLE and OMF South. To minimize the extent of mainline modification, a third track is proposed running alongside the mainline at an elevation closer to the selected OMF South elevation for compatibility with the yard-connecting tracks. The third track would have a connection to the mainline at the north and south ends only. The connection track would have No. 10 turnouts and be designed for 25 miles per hour. The connecting tracks and yard lead tracks would require a design variance for all vertical curve lengths. There are independent vertical track designs for the two OMF South elevation options.

Based on the current FWLE mainline design, irrespective of the construction option selected, the FWLE mainline will need to be modified to enable the connection of OMF South lead track turnouts at the required grade of 2 percent or less (Sound Transit 2018). The extent of mainline modification varies based on the OMF South site elevation, as shown in Table 2-6 below.

As of September 2020, FWLE project has accepted a change order to modify the profile to accommodate future lead track connections from OMF South at the landfill site that will meet the needs of either yard elevation of 365 feet or 380 feet.

TABLE 2-6
Track Summary

	Low Yard Elevation (365')	Medium Yard Elevation (380')
Northern Mainline Modifications*	Up to approximate 8' rise in elevated mainline over 3,200'.	Up to approximate 8' rise in elevated mainline over 3,200'.
Southern Mainline Modifications*	Up to approximate 10' lowering of at-grade mainline over 1,900'.	Up to approximate 5' lowering of at-grade mainline over 1,900'. Potential to avoid southern mainline modifications through further optimization.
Connecting/Third Track**	At-grade connecting track. Steep grades (~6%) and significant cut toward south end. Vertical curve length design variance required.	At-grade connecting track. Moderate grades. Vertical curve length design variance required.
Lead Tracks	At-grade lead tracks. North lead track has steep grades (~6%). Vertical curve length design variance required.	At-grade lead tracks. Moderate grades. Vertical curve length design variance required.
Constructability	More complex. Requires deep cut of existing landfill.	Least complex.
Cost	$$$$	$$$
Schedule	Potential longer duration.	Medium duration.

2.6.5 Potential Long-Term Settlement

The three subsurface construction design options to redevelop the Midway Landfill as OMF South will have different performance implications pertaining to potential future settlement. Without modification to the existing landfill, site settlement will have a significant negative impact on OMF South operation due to facility tolerances. The settlement design criteria for the OMF South evaluation is a maximum differential settlement of 0.75 inches over 100 feet and a maximum total settlement of 1 inch over a 50-year period. Settlement is considered over the long-term as major structural facilities for Link are to be designed for a 100-year design life, and buildings (including the OMF) are designed for continued operation over a minimum design life of 50 years. Each design option has been evaluated to determine the ability to meet this criteria which is consistent with the WSDOT Geotechnical Design Manual.

Landfilled material will continue to consolidate over time due to the compressive nature of the material, overburden weight, and biodegradation of the material. Settlement will likely be differential, or uneven, throughout a landfill as a result of variable refuse thickness and heterogeneous composition of the material. Without mitigation, settlement can negatively impact the integrity of building foundations, utilities, roadways, and trackways. The settlement evaluation provided by the OMFS Preliminary Geotechnical Recommendations (Sound Transit 2020e), estimates that the current landfill could have total settlements ranging from 1 to over 50 inches over the next 50 years.

The three options provide alternative designs to mitigate potential settlement as follows.

Low Platform: This option will be designed to support the OMF South buildings and track on a shaft-supported platform. The drilled shafts will be embedded in glacial soil encountered below the existing landfill. Long-term settlement impacts to the platform are not anticipated.

Hybrid 2: This option removes a majority of the landfill material, and the remaining portion of the landfill will be compacted with deep dynamic compaction ground improvement. The dynamic compaction ground improvement will reduce the compressibility of the remaining landfill material. To achieve the total and differential settlement design criteria, only 6 feet of compacted refuse will remain, which is a substantial change from the Midway Landfill Site Engineering Optimization Report (Sound Transit 2019b), which had a 40-foot refuse thickness remaining on site. The dynamic compaction of the remaining 6 feet of refuse material will compress the material and reduce post-construction total and differential settlement to achieve the design criteria. The competent backfill material placed and compacted over the remaining dynamically compacted refuse will reduce differential settlement experience at the ground surface, creating a more uniform settlement result. Buildings will be supported on shaft-supported platforms embedded in glacial soil consistent with the Low Platform option. The track will be supported on an on-grade concrete slab over the improved subgrade. The provision of an on-grade concrete slab in the yard areas will further mitigate differential impacts; however, impacts may become more pronounced at slab joints and interfaces.

Full Excavation: This option removes the degradable material from the refuse mass and backfills the OMF South subgrade with competent compacted granular material. Buildings and track will be supported by the backfilled subgrade. The option will eliminate settlement due to subgrade material degradation. Long-term settlements are not anticipated.

Based on the settlement tolerance guidance from Sound Transit, these three options to redevelop the Midway Landfill will be designed to meet the long-term maximum total and differential settlement design requirements.

3.0 Summary

This conceptual landfill site reuse plan is a high-level discussion of landfill preparation considerations pertaining to the potential redevelopment of the Midway Landfill as OMF South. The evaluation is presented as three possible subsurface construction design options to mitigate the landfill characteristics of the site.

- Low Platform – Low Structural Platform with Some Excavation
- Hybrid 2 – Excavation with Ground Improvements (Slab on Grade for Tracks and Buildings on Drilled Shaft)
- Full Excavation – Full Excavation and Backfill with Competent Soils

The three options were analyzed conceptually to inform decision-making as to whether redevelopment of the Midway Landfill is a viable option for OMF South and, if so, which subsurface construction option stands out as the preferred approach.

Sound Transit has identified four major risks that are unique to the Midway Landfill Alternative based on the site’s prior use as a disposal facility and classification as a Superfund site. These four risks are ground settlement, human health and safety, legal, and regulatory. Three of these risks (ground settlement, human health and safety, and regulatory) risks have been discussed and expanded upon in this plan to include risks to the cost and schedule for OMF South construction. Legal risks will be addressed under separate cover. The results are summarized below.

3.1 Ground Settlement

The conceptual design for each option has effectively mitigated the potential settlement risk; however, the Hybrid 2 option maintains more risk than the Low Platform and Full Excavation options. OMF South will be subject to the settlement of the remaining refuse associated with the Hybrid 2 option, and due to the irregular bottom surface of the landfill, there will be uncertainty as to whether the maximum refuse thickness has been achieved in all areas. Additionally, the small proportion of material to remain in place in comparison with the overall excavation quantity for Hybrid 2, and the required deep dynamic compaction to treat the material, likely does not provide a benefit that would outweigh the potential settlement risk.

The Low Platform and Full Excavation are preferred options to mitigate settlement.

3.2 Human Health and Safety

Human health and safety risk can be categorized as short-term and long-term. The short-term risk is related to OMF South construction, while the long-term risk would be for the operation of the facility into the foreseeable future.

The design of each option can effectively mitigate human health and safety risks; however, there are different risks associated with each option. The Low Platform option has the least short-term risk due to having the least amount of landfill disturbance in comparison with the other two options. The Low Platform option does have the most significant long-term risk because it leaves the largest amount of refuse material at the site and will continue to generate the most LFG.

The Hybrid 2 and Full Excavation options will handle and process significantly more refuse during construction than the Low Platform option, which increases the short-term risk associated with these two options to both construction workers and the public. The two options will have lower long-term risk due to having less contaminated material at the site and significantly less LFG generation potential. The Hybrid 2 option has the potential to generate more LFG than the Full Excavation option; however, the amount will likely be low.

3.3 Regulatory

The regulatory risks are similar for the three options. As identified above, there is a risk to the schedule based on the time required to get Ecology and/or EPA approval of the project relative to the ROD/CAP for the site, together with related agreements and permits, which is currently assumed to require 1 to 2 years.

The Hybrid 2 and Full Excavation options have greater short-term risks associated with construction and the regulatory uncertainties for refuse exposure, reuse, and work windows. The Low Platform option will have more long-term risk due to more ongoing cleanup management obligations throughout the life of the facility, and a greater risk to human health and the environment in the long-term due to the larger, unstable waste mass remaining in place.

3.4 Risks to Cost and Schedule

The high-level landfill preparation evaluation includes many unknowns that create risk that can significantly impact project cost and schedule. Some select items are discussed below.

- In-place material density is assumed to be 75 lb/cf. An increase in density will result in more truck trips based on a limit of 30 tons per truck trip and a longer export duration, increasing both schedule and cost. A decrease in density may require a larger container type to maintain the capacity of 30 tons per trip and would decrease the export duration, reducing schedule and cost. The Hybrid 2 and Full Excavation options are most at risk due to the large earthwork material quantities associated with these options.

- Material reuse is estimated at 40 percent. A decrease in reuse quantity will increase export and import requirements, increasing cost and extending the schedule. The opposite will occur for an increase in reusable material. The Hybrid 2 and Full Excavation options are most at risk due to the large earthwork material quantities associated with these options.
- Material export and disposal assumes a regulated Subtitle D landfill can accept the material. If a significant portion of the material is classified as hazardous requiring Subtitle C landfill disposal, costs will increase and disposal facility availability will become a concern. The Hybrid 2 and Full Excavation options are most at risk due to the large earthwork material quantities associated with these options.
- Intermodal facility availability for long-haul export of material is a risk. Available capacity has not been confirmed. Available capacity confirmed at this time may not be representative of when the facility is needed for OMF South construction. The facility may have access constraints based on disposal location and contractor negotiations. The location of the facility will impact haul routes, travel distances and times, and cost. If available capacity does not exist, intermodal facility development could become a project element, increasing cost and extending the schedule. The Hybrid 2 and Full Excavation options are most at risk due to the large earthwork material quantities associated with these options.

Detailed project costs and schedules will be addressed under separate cover.

3.5 Conclusions

Table 3-1 is based on the results of the landfill preparation evaluation and the summary of risks discussed in this section. The table content is relative among the three subsurface construction design options.

TABLE 3-1
Landfill Preparation Evaluation

Subsurface Construction Design Options	Settlement	Human Health and Safety	Regulatory	Cost (Landfill Preparation)	Schedule
Low Structural Platform with Some Excavation	Meets settlement criteria	Can effectively mitigate health and safety risks (with less short-term risk and more long-term risk)	More long-term regulatory risk associated with the waste mass remaining in place	Less risk due to design certainties	Less risk due to design certainties
Hybrid 2: Excavation with Ground Improvements (Slab on Grade for Tracks and Buildings on Drilled Shafts)	Meets settlement criteria (with more potential uncertainty)	Can effectively mitigate health and safety risks (more short-term risk, less long-term risk)	More short-term risk associated with regulatory requirements during construction	More risk due to material and handling unknowns	More risk due to material and handling unknowns
Full Excavation and Backfill with Competent Soils	Meets settlement criteria	Can effectively mitigate health and safety risks (more short-term risk, less long-term risk)	More short-term risk associated with regulatory requirements during construction	More risk due to material and handling unknowns	More risk due to material and handling unknowns

With the reduced amount of refuse left in place for the Hybrid 2 option, the option has become very similar to the Full Excavation option, except that by maintaining refuse below the facility, greater settlement risk exists. Additionally, the benefit of leaving the small portion of refuse in Hybrid 2 is outweighed by the cost associated with constructing buildings on shaft-supported platforms and track on a concrete slab on grade.

The evaluation indicates that the Low Platform and Full Excavation options may be preferred subsurface construction design options for the Midway Landfill Alternative. The Low Platform option generally carries more long-term risk as opposed to the Full Excavation, which has more emphasis on short-term risks. The Full Excavation option has more cost and schedule risk.

Executive Summary

This Human Health Risk Assessment (HHRA) has been prepared for the Midway Landfill as a potential site for Sound Transit's Operations and Maintenance Facility South (OMF South). Sound Transit is currently implementing a system-wide expansion of the Link light rail system and recently evaluated Midway Landfill as a potential site for the OMF South (HDR 2019a).

The purpose of the HHRA is to evaluate potential chronic health risks to Sound Transit personnel who work at the future site should it be selected for the OMF South and waste be maintained on site. Non-Toxicological hazards including acute, physical risks associated with constructing and operating the OMF South over a waste mass are also discussed.

Background

The Midway Landfill is located between Interstate-5 (I-5) and Highway 99, and South 252nd Street and South 246th Street in Kent, Washington. Between 1966 and 1983, approximately three million cubic yards of solid waste were deposited at the Midway Landfill. Records indicate that from 1980 to 1983 paint sludge, dyes, preservatives for decorative plants, alkaline wastes, oily sludges, waste coolant, truck steam cleaning wastes, and some oily wastes were deposited at the site (Parametrix 1988a). Approximately two million gallons of bulk industrial liquids from a single source were placed in the landfill (USEPA 2015a). However, the nature and type of industrial liquids disposed of in the Midway Landfill is not known. The City of Seattle (City) closed the landfill in 1983.

Cleanup work began in 1984 under the direction of the Washington State Department of Ecology (Ecology) and construction of a landfill gas extraction system began in 1985. The site was listed by the U.S. Environmental Protection Agency (USEPA) as a National Superfund Site in May 1986 (CERCLIS Identification Number: WAD 980638910). The City completed the cleanup in November 1992; however, because the Record of Decision (ROD) was not signed at that time, construction completion was not officially recognized until September 21, 2000.

Current and Future Site Uses

The landfill is currently owned by the City (USEPA 2000a) and operated by Seattle Public Utilities (SPU). The landfill is covered with a multilayered engineered cap (landfill cap) designed to reduce surface water infiltration into landfill waste and leachate discharge into underlying aquifers. A gas extraction system is in place and operating throughout the landfill to control subsurface migration of landfill gas (USEPA 2015a). Ecology oversees the City's operation and maintenance for the landfill cover system, gas extraction system, and surface water control systems constructed under the Consent Decree[1]. The landfill is fenced and no public access is allowed.

No one is known to be currently drinking the groundwater from any aquifer within almost a mile of the landfill and there are no current plans to use the groundwater near the landfill for drinking water. In addition, state regulations (WAC 173-160-171) do not allow any new private drinking water wells within 1,000 feet of a solid waste landfill or 100 feet of all other sources or potential sources of contamination and Ecology must be notified prior to the construction of any new well (USEPA 2015a).

OMF South Construction Approaches

As part of the process of evaluating the Midway Landfill for reuse as the OMF South site, Sound Transit has developed a preferred preliminary site layout and five construction design approaches for review and consideration. Differences in these five construction approaches could result in differences in occupational exposures to both toxic and non-toxic hazards at the OMF South. In order to streamline the exposure assessment step of the HHRA and the non-toxicological hazards evaluation, the five construction approaches are grouped into three future development concepts for the OMF South based on the potential exposures associated with each construction approach. Non-toxicological risks associated with each of these future development concepts are evaluated and discussed in Section 7. Human health risks are evaluated for the development concept that represents the worst case exposures scenario based on current site conditions and potentially complete routes of exposure.

Data Evaluation

Annual groundwater data collected between 2010 and 2014 from five wells located within or just outside of the landfill boundaries were available for review at the time of this assessment. These groundwater samples were analyzed for the following contaminants of interest (COIs): 1,4-dioxane, vinyl chloride, volatile organic compounds (VOCs), dissolved iron, and dissolved manganese. Detected concentrations of COIs in groundwater samples are shown in Table 1. Sample locations are shown in Figure 2-10 in Appendix A.

Monthly gas monitoring data collected from 106 onsite sample locations (e.g., landfill extraction wells and flares) between January 2015 and August 2019 were available for review at the time of this assessment. These landfill gas samples were analyzed for combustible gas (primarily methane), oxygen, carbon dioxide, temperature, static pressure, and other parameters. Methane gas concentrations in onsite landfill extraction wells and flares are summarized in Tables 2 and 3. Sample locations are shown in Figure 8 in Appendix A.

---

[1] A Consent Decree is a legal agreement entered into by the United States (through USEPA and the Department of Justice) and potentially responsible parties and lodged with a court. A consent decree dictates the final cleanup phase (remedial action) at a Superfund site.

Two available sources of data on the composition of subsurface gas in the vicinity of the Midway Landfill were identified during document review for this HHRA. These sources include a gas characterization study completed in 1988 as part of the Remedial Investigation (RI) (Parametrix 1988a), and a source emission evaluation completed in 1992 to quantify gas flare emission levels at the Midway Landfill (Am Test-Air Quality Inc. 1992). Gas samples collected in 1988 from onsite gas extraction wells and pre-combustion flares were analyzed for Hazardous Substance VOCs (Parametrix 1988a) and samples collected in 1992 from pre-combustion flare gas (flare inlet gas) were analyzed for VOCs (Am Test-Air Quality Inc. 1992). VOC concentrations in landfill gas samples are summarized in Tables 4, 5a and 6. Gas samples collected in 1988 and 1992 were also analyzed for inorganic gases (e.g., hydrogen sulfide and/or carbon monoxide). Hydrogen sulfide concentrations reported in the RI are shown in Table 5b. Carbon monoxide results were either not reported (Parametrix 1988a) or were not detected (Am Test-Air Quality Inc. 1992).

The quality of the available environmental data for the Midway Landfill was evaluated in the HHRA. Sample collection and analysis methods, sample location and frequency, and data characteristics were considered when evaluating overall data quality, appropriateness, and usability (USEPA 1992).

Based on evaluation of the available site data and supporting documents, the groundwater and methane datasets were determined to be of sufficient quality and reliability for use in this risk assessment. However, the data evaluation for this HHRA determined that the landfill gas data for VOCs and inorganic gases were not representative of current or future site conditions as they were collected more than 25 years ago from the landfill gas extraction system and thus do not represent concentrations of volatile gases to which future workers may be exposed. In addition, data collected from the landfill extraction system do not provide an appropriate measure of the concentrations that workers may be exposed to at the OMF South.

Exposure Assessment

The Midway Landfill will be used for occupational purposes if it is selected as the location of the future OMF South. As a result, various onsite workers (not residents) will have the greatest potential to contact impacted soil gas, groundwater, or air. These workers include long-term Onsite Office, Maintenance Shop, and Yard Workers and short-term Construction Workers.

Based on the knowledge of the current conditions at the Midway Landfill and planned future OMF South site uses, several potential occupational routes of exposure to COIs in landfill waste, gas, and groundwater were identified and evaluated (see the Conceptual Site Model, Figure 1).

The following routes of exposure were determined to be potentially complete for specific occupations at the OMF South:

- Inhalation of Indoor Air for Onsite Office and Maintenance Shop Workers,
- Inhalation of Air in Subsurface Confined Spaces (e.g., utility trenches and vaults) for Construction Workers,
- Inhalation of Outdoor Air for Maintenance Shop, Yard, and Construction Workers, and
- Direct Contact with Waste and Contaminated Soil for Construction Workers

Groundwater ingestion was determined to be an incomplete route of exposure because no one is known to be drinking groundwater from any aquifer within almost a mile of the landfill (USEPA 2015a), there are no water supply wells at the landfill, and state regulations (WAC 173-160-171) do not allow the development of drinking water wells in the vicinity of a landfill.

These potential routes of exposure are based on the assumptions that construction of the OMF South may result in future site conditions that could allow for vapor intrusion from subsurface gas and underlying groundwater to indoor air.

Contaminants of Potential Concern

Maximum concentrations of COIs detected in groundwater and landfill gas were compared to occupational screening levels for potentially complete routes of exposures in order to identify Contaminants of Potential Concern (COPCs). COPCs are those contaminants with the potential to cause adverse health effects in workers who are exposed to them over an extended period of time. These occupational screening levels were reviewed to verify that they were sufficiently protective of the occupational exposures expected to occur at the OMF South.

Groundwater data were compared to occupational screening levels for vapor intrusion to indoor air (e.g., MTCA Method C Groundwater Vapor Intrusion screening levels and the USEPA Worker Air VISLs for Groundwater) (see in Table 1). No COIs in groundwater exceed these screening levels.

There are no toxicity- or risk-based screening levels for methane concentrations; therefore, no comparisons were made for methane concentrations in landfill gas. In addition, due to the absence of representative landfill gas results for VOCs and inorganic gases, no comparisons were made between concentrations of these COIs in landfill gas and applicable risk-based screening levels.

As a result, no COPCs were identified in groundwater or landfill gas for further quantitative risk assessment.

Toxicological Assessment

Although no COPCs were identified for the Midway Landfill, toxicity information for those VOCs in landfill gas that were detected frequently and at high concentrations in previous investigations (Parametrix 1988a; Am Test-Air Quality Inc. 1992) is included in the Toxicity Assessment for informational purposes only. A toxicity profile for methane gas and a brief summary of the non-toxicological hazards associated with methane gas (flammability and asphyxiation) are also included.

HHRA Findings

The OMF South will be connected to the municipal water system and will not use groundwater at the facility. Groundwater ingestion is considered to be an incomplete route of exposure for all occupational exposure scenarios at the OMF South and therefore groundwater ingestion does not pose a chronic health risk to any OMF South worker.

Exposure to vapors from landfill gas and groundwater were considered as a potentially complete route of exposure under the worst-case scenario assumption that a long-term failure in engineered protections (including the landfill cap and gas collection system) occurs at the OMF South, allowing for vapor intrusion from subsurface gas and underlying groundwater to indoor air.

Based on the comparison of maximum concentrations of COIs detected in groundwater to applicable risk-based screening levels, occupational exposure to COIs in groundwater at the Midway Landfill via vapor intrusion is not expected to result in adverse chronic health effects for any OMF South worker.

In addition, occupational exposure to methane gas is not expected to result in adverse chronic health effects due to the relatively non-toxic nature of the gas. However, other occupational hazards associated with methane gas, such as flammability, at the Midway Landfill may need to be considered and addressed through risk management efforts if Sound Transit selects the site for the future OMF South.

A high level of uncertainty remains regarding the potential risks associated with occupational exposures to VOCs and inorganic gases at the site due to a lack of sufficient and reliable data necessary to characterize human health risks and uncertainty regarding the potential for occupational exposure to landfill gases based on current and future site conditions and engineered controls.

In order to effectively quantify the risk associated with occupational exposures to COIs in landfill gas, additional sampling is needed to characterize site conditions and identify potential routes of exposure. Future sampling of landfill gas constituents should be conducted following an approach that generates the appropriate environmental data needed to characterize occupational exposures and evaluate potential health risks at the OMF South (e.g., post-construction sub-slab soil gas and/or indoor air sampling).

Pre-construction sampling of flare inlet gas and gas extraction wells could also be conducted to provide information on the COIs present in landfill gas at this time; however, concentrations of COIs in samples collected from the landfill gas collection system would not be appropriate for use in the assessment of occupational exposures at the OMF South as they are likely not representative of concentrations in the subsurface that may pose an unacceptable threat to indoor air quality in site buildings. At this point, quantification of any long-term worker risk is premature until representative data can be acquired.

In order to better assess current concentrations of COIs in gas collected from the landfill, if requested by Sound Transit, follow-up sampling and analysis could be conducted. Potential landfill gas sampling options are discussed in Appendix B.

Non-Toxicological Hazards Evaluation

Some of the primary non-toxicological risk factors associated with redevelopment on a landfill include methane explosion and subsurface fire risk, seismic considerations, and occupational exposures to site COIs and environmental hazards during construction activities.

Methane Explosion Risk

Explosion risk is present at the site and needs to be mitigated through engineered controls. Common means for protection would be the re-establishment of the landfill cap and gas collection system impacted during construction of the OMF South. Additional engineered protections can also be incorporated into the OMF South design to mitigate the risk associated with a potential landfill cap leak and/or gas collection system failure for areas in contact with the landfill surface. Depending on the selected construction design, these engineered protections may include an independent, under slab methane barrier with passive gas ventilation and/or gas sensors installed in occupied areas and in areas where site operations provide an ignition source.

Methane migration to in-ground, non-building, confined spaces could occur through a leak in the landfill cap resulting in a methane explosion or asphyxiation hazard. These hazards can be managed through adherence to required confined space entry procedures, including monitoring of methane and oxygen concentrations prior to entry.

Seismic Considerations

Stability concerns have not been identified at Midway Landfill. The site configuration is primarily a backfill of a previous excavation and site slopes have no reported signs of instability. All of the construction design approaches for the OMF South are expected to improve site stability and further geotechnical analysis can be performed to evaluate site seismic and static stability with the planned landfill modifications and OMF South loading.

Hazards Associated with Construction Activities

The construction of the OMF South under all of the construction design approaches requires the disruption of established remedial systems which, without adequate and proper controls, could temporarily expose construction workers to solid waste and landfill gas and may generate dust and contaminated runoff that could impact the surrounding environment. Air intrusion into the landfill will also need to be prevented since this could result in a landfill fire. Appropriate planning and an adherence to applicable regulations will be required to provide continued protection of human health and the environment during construction of the OMF South.

An Environmental Protection Plan will likely be required to establish procedures to manage and monitor the waste excavation and handling process. A project-specific Health and Safety Plan and Hazardous Waste Operations and Emergency Response Standard (HAZWOPER) training will be required.

Conclusions

The HHRA found that occupational exposures to VOCs in groundwater and to methane in landfill gas are not expected to result in adverse chronic health effects for any OMF South worker. However, the potential risk associated with occupational exposures to COIs in landfill gases could not be characterized due to a lack of representative data. In order to quantify occupational risk at the OMF South, post-construction sampling of VOCs and inorganic gases is needed (e.g., sub-slab soil gas and/or indoor air sampling) to provide an appropriate measure of the concentrations that workers may be exposed to at the OMF South.

In order to assess current COI concentrations in landfill gas, a pre-construction landfill gas investigation could be conducted. Potential landfill gas sampling options are discussed in Appendix B.

The non-toxicological hazards evaluated for the Midway Landfill can largely be managed through appropriate engineered protections, health and safety protocols, construction design standards, and site control and environmental protection plans. Risk management approaches for non-toxicological hazards will need to be developed based on the final selected OMF South construction approach.

1.0 Introduction

This Human Health Risk Assessment (HHRA) has been prepared for the Midway Landfill as a potential site for Sound Transit's Operations and Maintenance Facility South (OMF South).

Sound Transit is currently implementing a system-wide expansion of the Link light rail system and is evaluating the Midway Landfill as a potential site for the OMF South (HDR 2019a). The purpose of the HHRA is to evaluate potential chronic health risks to Sound Transit personnel who work at the future site should it be selected for the OMF South and waste be maintained on site. Non-Toxicological hazards including acute, physical risks associated with constructing and operating the OMF South over a waste mass are also discussed briefly.

From this point forward, this report is organized in the following sections described below. The key components of the HHRA are discussed in Sections 2 through 6 and a discussion of non-toxicological hazards is contained in Section 7.

Section 2 Background provides a brief summary of background information on the Midway Landfill, including the site setting, history, geology, and hydrogeology of the area, current and reasonably likely future beneficial uses of land and water, and current redevelopment conceptual designs for OMF South.

Section 3 Data Evaluation provides a summary of the nature and extent of contamination at the Midway Landfill, past site investigation and characterization activities, contaminants of interest (COIs), and environmental data available for use in the risk assessment. Data quality is evaluated for appropriateness and usability and data gaps are identified in this Section.

Section 4 Exposure Assessment provides an estimation of the amount, frequency, duration, and routes of exposure that an OMF South worker may have to contaminants found at the Midway Landfill. This section describes the scenarios in which OMF South workers could be exposed to contaminants based on likely future site use and compares concentrations of COIs in specific media to risk-based screening levels in order to identify contaminants of potential concern (COPCs) at the landfill.

Section 5 Toxicity Assessment summarizes the nature and degree of toxicity of each COPC in order to characterize potential chronic health risks associated with exposure to COPCs at the Midway Landfill. Two types of health effects are discussed: 1) non-carcinogenic health effects, and 2) carcinogenic health effects. The same chemical may exert both kinds of effects.

Section 6 HHRA Findings provides an overview and discussion of the nature and magnitude of potential risks to OMF South workers at the Midway Landfill.

Section 7 Non-Toxicological Hazards Evaluation describes other risk factors associated with siting the OMF South at the Midway Landfill including a discussion of methane explosion hazards, seismic considerations, and worker health and safety during construction activities.

2.0 Background

2.1 Site Setting

The Midway Landfill is located between Interstate-5 (I-5) and Highway 99 and South 252nd Street and South 246th Street in Kent, Washington. The landfill is roughly 60 acres in size with solid waste buried on about 40 acres at depths of up to 100 feet. Between 1966 and 1983, approximately three million cubic yards of solid waste were deposited at the Midway Landfill. The landfill is currently owned by the City of Seattle (City) (USEPA 2000a) and operated by Seattle Public Utilities (SPU).

The landfill is covered with a multilayered engineered cap (landfill cap) designed to reduce surface water infiltration into landfill waste and leachate discharge into underlying aquifers. The landfill is fenced and no public access is allowed. A gas extraction system is in place and operating throughout the landfill to control subsurface migration of landfill gas (USEPA 2015a).

Surrounding land use is primarily commercial and residential. Commercial businesses, light industry and manufacturing border Highway 99. Most of the nearby residences are detached single-family dwellings, with some multi-unit residential developments and mobile home parks in the vicinity. Two schools, Sunnycrest Elementary School and Parkside Elementary School, and a city park, Linda Heights Park, are within a half-mile of the landfill (USEPA 2015a).

2.2 Site History

The site of the current Midway Landfill was operated as a gravel pit from 1945 until 1966. In 1966, the City leased the site for use as a landfill for demolition materials, wood waste, and other slowly decomposing materials (USEPA 2015a). Records indicate that from 1980 to 1983 paint sludge, dyes, preservatives for decorative plants, alkaline wastes, oily sludges, waste coolant, truck steam cleaning wastes, and some oily wastes were deposited at the site (Parametrix 1988a). Approximately two million gallons of bulk industrial liquids from a single source were placed in the landfill (USEPA 2015a). The nature and type of industrial liquids disposed of in the Midway Landfill is not known. The City closed the landfill in 1983.

Following closure of the landfill, the City began sampling groundwater and landfill gas in and around the site. Organic and inorganic contaminants were detected in groundwater from monitoring wells and in gas samples from gas probes both within and outside the landfill boundary (USEPA 2015a).

Cleanup work began in 1984 under the direction of the Washington State Department of Ecology (Ecology) and construction of a landfill gas extraction system began in 1985. The site was listed by the U.S. Environmental Protection Agency (USEPA) as a National Superfund Site in

May 1986 (CERCLIS Identification Number: WAD 980638910). In September 1988, the City and Ecology prepared a Remedial Investigation (RI) and a Remedial Action Feasibility Study (FS) (USEPA 2015a).

The RI investigated the impact of the landfill on the environment and included monitoring of the landfill gas, air emissions, leachate, groundwater, and surface water on or adjacent to the site (Parametrix 1988a). Findings of the RI are summarized briefly below.

- Gas samples from onsite gas extraction wells and pre-combustion flare were analyzed for a number of contaminants including numerous USEPA Hazardous Substances List (HSL) volatile organic compounds (VOCs). The VOCs found most frequently and in the highest concentrations in onsite subsurface gas included ethylbenzene, vinyl chloride, total xylenes, toluene, and benzene. The inorganic gases, hydrogen sulfide and carbon monoxide, were also reported present in onsite gas in the low parts per million (ppm) range (Parametrix 1988a).
- Landfill emissions to ambient air were evaluated by comparing contaminant concentrations in samples collected from upwind and downwind of the Midway Landfill. Samples were analyzed for VOCs. Many contaminants were found at higher concentrations upwind of the landfill and at offsite locations that were not downwind from the landfill which indicated the presence of offsite sources of emissions unrelated to the Midway Landfill (e.g., I-5 and Highway 99). In addition, ambient air quality near the landfill was not found to be measurably different from typical urban air and onsite air quality monitoring found no evidence of gas emission through the surface of the landfill sufficient to cause adverse ambient air impacts (Parametrix 1988a).
- Leachate generated by infiltration from precipitation and direct discharge of stormwater into the solid waste contained in the landfill was sampled from three wells and analyzed for USEPA HSL contaminants, including metals, VOCs, pesticides, and other potentially hazardous substances during the RI. Leachate samples were found to contain a variety of HSL compounds at trace levels (Parametrix 1988a).
- Groundwater samples were collected from approximately 40 locations in and around the landfill including 29 monitoring wells, 8 boreholes, and 2 private wells. Samples were analyzed for conventional water quality parameters as well as HSL compounds. A number of HSL VOCs were found in groundwater and five wells exceeded drinking water standards for one to three VOCs each. The VOCs detected in groundwater fall into three major groups: ketones, benzenes, and chlorinated solvents. The specific compounds detected are all involved in the use of paints, varnishes, resins and plastics, either as solvents, swelling agents, thinners, or removers (Parametrix 1988a).

- The RI found no evidence of offsite transport of contaminants in surface water or leachate contamination into nearby seeps or springs (Parametrix 1988a).

In May 1990, the City and Ecology entered into a Consent Decree pursuant to State of Washington Model Toxics Control Act (MTCA). In this Consent Decree, the City agreed to perform specific cleanup work. This cleanup work, or remedial action, had the following elements:

1) A multi-layered landfill cover system (landfill cap) designed to reduce surface water infiltration into the landfill and the release of hazardous emissions from the landfill (completed in May 1991) (USEPA 2000a, 2015a);
2) An active gas extraction system (construction began in September 1985 and was completed in March 1991) (USEPA 2015a);
3) A surface water management system to control surface water drainage and prevent surface water from infiltrating the landfill including a 10 million-gallon stormwater detention pond with a permanent dewatering system, a controlled discharge structure, and rerouting of stormwater from the Linda Heights Park drain and I-5 to the detention pond to prevent it from entering the landfill (completed in 1991) (USEPA 2015a); and,
4) A comprehensive plan for short- and long-term operations and maintenance for the systems constructed under the Consent Decree (prepared by the City and approved by Ecology in April 1992) (USEPA 2015a).

The City completed the cleanup in November 1992. However, since the Record of Decision (ROD) was not signed at that time, construction completion was not officially recognized until September 21, 2000.

An amendment to the 1990 Consent Decree specified a requirement to implement a compliance monitoring plan at the landfill to track the presence, concentration, and migration of groundwater contaminants both upgradient and downgradient of the landfill and to assess the effectiveness of the remedial action. Compliance monitoring began in 1990. In addition, the City initiated performance monitoring in 1989 to track the response of landfill leachate levels and shallow groundwater levels to the implementation actions required by the Consent Decree. Both compliance and performance monitoring programs are ongoing (USEPA 2000a, 2015a).

Landfill gas monitoring (which consists of checks for concentration, composition, temperature, flow, and velocity of gases in and around the landfill) is conducted by the City on a regular basis (USEPA 2000a, 2015a).

Available post-cleanup groundwater and landfill gas monitoring results are discussed further in Section 3.

2.3 Site Conditions

Information on the site geology, site hydrogeology, surface water and stormwater systems, landfill cap, and landfill gas extraction system is included in numerous site documents and is summarized in the sections below.

2.3.1 Site Geology and Subsurface Conditions

The Midway Landfill occupies a shallow, bowl-shaped depression (a former gravel pit) near the crest of a narrow north-south trending glacier feature known as the Des Moines Drift Plain (USEPA 2015a). The Des Moines Drift Plain lies between the Olympic Mountains on the west and the Cascade Mountains on the east and is underlain by a thick sequence of Quaternary glacial, fluvial (riverine), and lacustrine (lake bed) deposits overlying Tertiary volcanic and sedimentary bedrock (USEPA 2000a). Depth to bedrock is thought to exceed 1,000 feet near Midway Landfill (USEPA 2015a).

Subsurface materials under the site are of glacial origin and consist for the most part of mixed sands and gravels, with some silt and clay (Parametrix 1988a). The ground surface of the landfill has been modified by the placement of waste and cover material.

Based on studies of the area and analysis of geological samples collected during the installation of monitoring wells for the RI, nine stratigraphically distinct deposits were identified from the land surface down approximately 400 feet to sediments that are near current mean sea level (MSL). Because of the complex layering in all the sediments underlying the landfill, vertical and horizontal permeabilities are highly variable and produce a complex groundwater flow pattern (USEPA 2000a).

2.3.2 Site Hydrogeology

Groundwater movement within and below the landfill has been characterized to an approximate depth of 300 to 350 feet below ground surface (bgs) (50 to 100 feet above MSL). Several groundwater units have been identified within this interval. From shallowest to deepest these aquifers are: Shallow Groundwater; Saturated Refuse; Upper Gravel Aquifer (UGA); Sand Aquifer (SA); Southern Gravel Aquifer (SGA); and Northern Gravel Aquifer (NGA) (USEPA 2015a).

2.3.2.1 Shallow Groundwater

According to the ROD (USEPA 2000a), this zone of saturation is shallow, discontinuous lenses of groundwater. The majority of these shallow zones are found north and south of the landfill. The general water elevation of the shallow groundwater zone adjacent to the landfill is generally at about 325 feet above MSL north and south of the landfill, and lower, and more discontinuous to the east and west (USEPA 2000a).

The landfill's detention pond dewatering system affects shallow groundwater flow through the northern periphery of the landfill. Shallow groundwater north of the landfill (at 320 feet or above) is captured by the dewatering system and routed to North McSorley Creek. The dewatering system limits the shallow groundwater that discharges into the landfill from the north (USEPA 2000a).

2.3.2.2 Saturated Refuse

Prior to the remediation required by the 1990 Consent Decree, the major sources of water to the landfill were: surface water infiltrating from the landfill surface and from areas north of the landfill that drained into the landfill; stormwater discharge from the Linda Heights neighborhood, and I-5 drainage that was routed into the landfill as part of the construction of I-5; and shallow groundwater from north and south of the landfill (USEPA 2000a).

The Saturated Refuse consists of leachate within the landfill and is located below elevations of approximately 325 feet. Flow in the Saturated Refuse is generally from the north and west toward the south-central section of the landfill, where the pit excavations were deepest. Leachate likely discharges vertically throughout much of the landfill base, but the greatest volume of vertical flow is in the south-central area, where leachate discharges to the underlying UGA (USEPA 2000a).

Since construction of the engineered cap and stormwater diversion systems, the majority of surface water that entered the landfill has been diverted and leachate levels have dropped by as much as 20 feet (USEPA 2000a).

2.3.2.3 Upper Gravel Aquifer

The UGA is located at the base of the landfill (100 to 170 feet bgs) and consists of interbedded zones of permeable gravels and less permeable mixtures of silt, sand, and gravels. Leachate from the landfill discharges into the underlying UGA. Groundwater flow in the UGA is generally from both the north and south inward toward an area beneath the southern end of the landfill where the groundwater discharges downward into the underlying SA. The UGA and SA are separated by a discontinuous layer of fine-grained silt, clayey silt, and silty fine sand that is present throughout most of the study area known as the Upper Silt Aquitard. Vertical flow from the UGA into the SA is most pronounced where the aquitard is absent (e.g., beneath the southern end of the landfill) (USEPA 2000a).

The remediation required by the 1990 Consent Decree and the dewatering of the refuse have greatly reduced the amount of recharge entering the UGA. Within the landfill footprint and around the perimeter, the UGA monitoring wells have been dry since 1992 (USEPA 2000a).

The UGA beneath the landfill is under vacuum from the landfill gas extraction system which helps to reduce volatile organics in leachate from being released to the underlying groundwater system (USEPA 2000a).

2.3.2.4 Sand Aquifer

The SA occurs as a widespread deposit of interbedded sands and silts approximately 200 to 300 feet bgs. Flow in this aquifer is generally from the north and west to the southeast toward a hydraulic sink that occurs across a broad area beneath the southern part of the landfill and extends several hundred feet to the east. Groundwater entering this sink flows downward into the SGA (USEPA 2000a).

2.3.2.5 Southern Gravel Aquifer

The SA and SGA are separated by the Lower Silt Aquitard. Similar to the Upper Silt Aquitard, the Lower Silt Aquitard is discontinuous in places allowing for the downward flow from the SA into the SGA (USEPA 2000a).

The SGA is found beneath the southern half of the landfill at approximately 300 to 350 feet bgs and extends to the east, south, and west. It consists of permeable sands and gravel interbedded with silts and silty gravel. The SGA appears to be recharged by the SA and by lateral flow from the south. A groundwater mound in the SGA, below the hydraulic sink in the SA, is believed to be an expression of regional flow through the sink (USEPA 2000a). Groundwater flow is generally northeast-northwest and the SGA eventually discharges west to Puget Sound and east to the Green River Valley (USEPA 2015a).

2.3.2.6 Northern Gravel Aquifer

The NGA is found beneath the northern half of the landfill at approximately 300 to 350 feet bgs and extends to the north and northeast. Similar to the SGA, the NGA consists of permeable sands and gravel interbedded with silts and silty gravel. Flow from the NGA is generally from north to south toward the SGA and, like SGA, the NGA eventually discharges to Puget Sound and the Green River Valley (USEPA 2015a).

2.3.3 Surface Water and Storm Water System

Midway Creek is located northeast of the landfill, and two other streams, the north and south forks of McSorley Creek, are located to the west and southwest, respectively (USEPA 2015a).

There are no major surface water bodies in the immediate vicinity of the Midway Landfill. The closest are Lake Fenwick, located approximately one mile to the southeast, and Star Lake, located approximately 1.5 miles to the south (USEPA 2015a).

A six-acre wetland, the Parkside Wetland, located to the east of the Parkside Elementary School and west of the landfill is a naturally occurring detention basin for local surface water runoff, primarily from the west side of Highway 99 (USEPA 2000a).

A stormwater collection system was installed as part of the 1990 Consent Decree to control surface water drainage and prevent surface water infiltration into the landfill. The stormwater collection system includes a 10 million-gallon stormwater detention pond with a permanent dewatering system, a controlled discharge structure, and rerouting of clean stormwater from the site into McSorley Creek, which is a salmon-bearing stream containing coho and chum salmon, steelhead and cutthroat trout (USEPA 2000a).

2.3.4 Landfill Cover System

The Midway Landfill is currently covered by a multi-layered landfill cap comprised (from bottom to top) of a 12-inch-thick layer of low permeability soil/clay material, a 50-mil high-density polyethylene (HDPE) flexible membrane, drainage net, filter fabric, a 12-inch-thick drainage layer, and a 12-inch-thick topsoil layer planted with shallow rooted grasses (USEPA 2000a, 2015a). The landfill cap reduces surface water infiltration into the landfill and controls the release of hazardous emissions from the landfill.

2.3.5 Landfill Gas Extraction System

Construction of an active gas extraction system at the Midway Landfill began in September 1985 and was completed in March 1991. The gas extraction system originally included 87 gas extraction wells; however, 31 offsite gas extraction wells located outside of the landfill footprint in native soil have since been abandoned or capped because offsite gas has been removed from the offsite locations and is currently controlled via onsite extraction wells. Landfill gas is extracted through the onsite extraction wells at the landfill and routed to a permanent blower/flare system where the extracted gas is supplemented with natural gas and then burned before discharge to the atmosphere (USEPA 2000a, 2015a). The natural gas is needed for combustion due to the low volume of landfill gas currently generated at the site. It was noted in the Third Five-Year Review of the Midway Landfill (USEPA 2015a) that during a June 2015 site inspection, the mechanical equipment for the gas extraction system appeared to be in good operating condition.

2.3.6 Operations and Maintenance Requirements

Ecology oversees the City’s operation and maintenance for the landfill cover system, gas extraction system, and surface water control systems constructed under the Consent Decree. The short-term and long-term operation and maintenance requirements for Midway Landfill are described in the Midway Landfill Operation and Maintenance Manual (Parametrix 1992) which was approved by Ecology in April 1992. The manual addresses operation and maintenance of all components of the remedy including: gas system, surface water systems, pump stations, landfill cover system, and roadway and site control. There are no reporting requirements associated with the landfill cap, gas collection system, or surface water drainage system; however, routine maintenance records are kept onsite (USEPA 2015a). The Third Five-Year Review noted that the Midway Landfill Operations and Maintenance Manual has not been updated since 1992 and should be updated to include the current landfill gas sampling locations and schedule and location of operational gas extraction wells (USEPA 2015a).

2.4 Beneficial Uses of Land and Water

The following sections briefly describe the current and future uses of land and water at the Midway Landfill site.

2.4.1 Current and Future Land Uses

Currently the landfill is capped and fenced. No public access is allowed.

As part of the Consent Decree (Ecology 1990) and as described in the ROD (USEPA 2000a), the City is required to place a notice in the records of real property kept by the King County auditor alerting any future purchaser of the landfill property, in perpetuity, that this property had been used as a landfill, was on the USEPA’s National Priorities List, and that future use of the property is restricted. The use restriction shall comply with the post-closure use restrictions under the State of Washington’s Criteria for Municipal Solid Waste Landfills, Washington Administrative Code (WAC) 173-351-500. The City is responsible for ensuring that future owners and operators are made aware of these restrictions and that restrictions remain in effect and are complied with even in the event the property is sold or transferred (USEPA 2015a).

The City is required to ensure continued operation and maintenance of all components of the remedy if any portion of the property is sold, leased, transferred, or otherwise conveyed (USEPA 2015a).

Sound Transit is currently implementing a system-wide expansion of the Link light rail system and recently evaluated Midway Landfill as a potential site for the OMF South (HDR 2019a). The current redevelopment conceptual designs for the Midway Landfill would construct the OMF South at the site. The proposed OMF South site is described in more detail in Section 2.4.3 below.

2.4.2 Current and Future Water Uses

According to the Third Five-Year Review for the Midway Landfill Superfund Site, no one is known to be drinking the groundwater from any aquifer within almost a mile of the landfill and there are no current plans to use the groundwater near the landfill for drinking water. The closest wells currently in use for drinking water are the Lake Fenwick wells almost one mile southeast of the Midway Landfill (USEPA 2015a).

State regulations (WAC 173-160-171) do not allow any new private drinking water wells within 1,000 feet of a solid waste landfill or 100 feet of all other sources or potential sources of contamination and Ecology must be notified prior to the construction of any new well (USEPA 2015a). Per the National Oil and Hazardous Substances Pollution Contingency Plan (NCP), the Midway Landfill is considered a waste management area and thus is not considered a future drinking water source by the USEPA (USEPA 2015a).

2.4.3 Operation and Maintenance Facility South (OMF South)

As part of the process of evaluating the Midway Landfill for reuse as the OMF South site, Sound Transit has developed a preferred preliminary site layout and five construction design approaches for review and consideration. The preliminary site OMF South layout is approximately 68 total acres including an Operation and Maintenance Building and the capability to store and maintain 144 vehicles. The site also includes a 5-acre storage area with a Maintenance of Way Warehouse. The total site area includes the lead tracks from the mainline to the site and other support areas. The five construction approaches include:

- **Approach 1:** High structural platform with no excavation
- **Approach 2:** Low structural platform with some excavation
- **Approach 3:** Hybrid 1: Excavation with ground improvements (buildings on drilled shafts)
- **Approach 4:** Hybrid 2: Excavation with ground improvements (slab-on-grade for tracks and buildings on drilled shafts)
- **Approach 5:** Full excavation and backfill with competent soils

The site layout and construction approaches are discussed in detail in the Midway Landfill Site Engineering Optimization Report (HDR 2019b).

The horizontal layout of the OMF South is consistent between all of the construction approaches. However, the construction approaches differ vertically based on alternative construction designs developed to mitigate landfill settlement and other environmental impacts associated with construction in a landfill. The differences in vertical construction approaches could result in differences in occupational exposures to both toxic and non-toxic hazards at the OMF South.

In order to streamline the exposure assessment step of the HHRA and the non-toxicological hazards evaluation, the construction approaches listed above are grouped into three future development concepts for the OMF South based on the potential exposures associated with each construction approach. The concepts are as follows.

> **Concept 1:** OMF South built on an elevated structural platform. This concept includes an elevated platform constructed on shafts or pilings that are installed through the landfill cap and the underlying waste material. The landfill cap will be restored at penetrations and the gas system and other environmental controls will be preserved. This concept represents the high structural platform construction approach (Approach 1).
>
> **Concept 2:** OMF South built on a slab on the surface of the landfill following full excavation and removal of underlying landfill waste. This concept includes removal of the landfill cap and underlying solid waste, screening and reuse of contaminated, but competent, soils contained in the landfill as fill, reconstruction of the landfill cap, reconstruction of environmental controls, and construction of a slab foundation. This concept represents the full excavation and backfill with competent soils construction approach (Approach 5).
>
> **Concept 3:** This concept is a combination of Concepts 1 and 2 and will include removal of the landfill cap, partial removal of underlying solid waste, screening and reuse of contaminated, but competent, soils contained in the excavated portion of the landfill as fill, reconstruction of the landfill cap, reconstruction of environmental controls, and construction of the OMF South on a combination of slab foundation and an elevated platform on shafts or pilings. This concept represents the low structural platform, Hybrid 1, and Hybrid 2 construction approaches (Approaches 2, 3, and 4).

The activities carried out at the OMF South are generally expected to range from administrative work, warehouse management, and vehicle maintenance to track and yard maintenance. Work environments will vary between an office, shop, warehouse, or the outdoors. Regardless of the implemented construction design, Sound Transit operations work activities will remain above the landfill cap and are not expected to disrupt in-place remedies.

Non-toxicological risks associated with each of these future development concepts are evaluated and discussed in Section 7. Human health risks are evaluated for the worst case exposures scenario, which is represented by Concept 3, based on current site conditions and potentially complete routes of exposure.

3.0 Data Evaluation

The first step in the data evaluation process for the Midway Landfill is to identify any and all available environmental data for COIs for use in this HHRA[2]. The following reports contain relevant environmental data; however, some parts of these reports were not available for review at the time of this assessment resulting in a lack of supporting information needed to conduct a full data evaluation[3]. The reports that contained environmental data and that were available for review (full or partial) include:

- Midway Landfill Remedial Investigation Summary Report. Parametrix. July 1988.
- Source Emissions Evaluation for the Midway Sanitary Landfill, Landfill Gas Flare Testing. Am Test-Air Quality Inc. February 1992.
- Midway Landfill EPA ID: WAD980638910 OU 01, Kent, Washington Record of Decision. USEPA. September 2000.
- ARI Analytical Data Quality Review for the Midway Groundwater Monitoring Event 57. Analytical Resources, Incorporated (ARI). May 2010.
- Midway Landfill Groundwater Monitoring 2010 Annual Report. Parametrix. July 2011.
- Midway Landfill Groundwater Monitoring Status Report 2010-2014. Parametrix. May 2015.
- Third Five-Year Review for the Midway Landfill Superfund Site, Kent, Washington. USEPA Region 10. September 2015.

The second step in the data evaluation process is to review the available data to determine whether they are of sufficient quality and reliability to support a quantitative comparison to recommended risk-based screening levels (USEPA 1992). The following questions are considered when evaluating data quality:

- Were the samples collected and analyzed by reliable and acceptable methods?
- How old are the data? Are the data representative of current site conditions?

---

[2] At the time of this assessment, the most recent compliance groundwater monitoring data (2015 to present) were not publicly available; therefore, the most current publicly available compliance groundwater monitoring data from 2010-2014 were evaluated.

[3] The process for requesting and obtaining some reports or supporting information from Ecology and SPU was prohibitive given the timeline of this assessment.

- Were the laboratory reporting limits sufficiently low for comparison with applicable screening levels?
- Were multiple locations sampled to assess spatial variability of the results?
- Were multiple sampling events conducted to assess temporal variability of the results?

These considerations are discussed for available groundwater and landfill gas data in the data review and summary section (Section 3.2) below.

3.1 Contaminants of Interest

The RI and subsequent groundwater and landfill gas monitoring evaluated a wide range of potential contaminants in groundwater and landfill gas (Parametrix 1988a, 2011, and 2015; ARI 2010; Am Test-Air Quality Inc. 1992). Those chemicals detected in groundwater and landfill gas and reported in the documents listed above in this section are considered COIs for the purposes of this HHRA. These COIs are shown in Tables 1 through 6 of this report.

3.2 Data Review and Summary

3.2.1 Groundwater Data Review

Under the ROD, the City has conducted performance and compliance groundwater monitoring programs at the Midway Landfill since 1989. Groundwater chemistry monitoring was initiated in February 1990 and has been conducted on a quarterly or semi-annual basis until 2010 when the monitoring frequency was changed to annual sampling in the spring (April or May) (Parametrix 2015). Groundwater samples are collected from monitoring wells located upgradient and downgradient of the landfill. The current groundwater chemistry monitoring program consists of the annual sampling of 11 wells completed in the UGA, SA, and SGA. Annual sampling events were conducted by SPU staff in May of each year. Four additional wells are part of the monitoring program but are not currently sampled because they are dry. Groundwater samples are analyzed for conventional parameters, metals, and VOCs (Parametrix 2015).

At the time of this assessment, annual groundwater results from 2010 through 2014 were available for review in the Midway Landfill Groundwater Monitoring Status Report 2010-2014 (Parametrix 2015) and the Midway Landfill Groundwater Monitoring 2010 Annual Report (Parametrix 2011). Original laboratory results were also available for the May 2010 sampling event (ARI 2010). While more recent groundwater data (2015 to the present) have been collected as part of the performance and compliance groundwater monitoring programs, these data were not available for review at the time of this assessment.

Per the Midway Landfill Groundwater Monitoring Status Report 2010-2014 (Parametrix 2015), all samples were collected in accordance with the methods outlined in the approved Midway

Landfill Monitoring Plan (Parametrix 2000). The Midway Landfill Monitoring Plan (Parametrix 2000) and Appendix C of the Midway Landfill Groundwater Monitoring Status Report 2010-2014, which contains the data quality summaries for groundwater results from 2010 through 2014, were not available for review at the time of this assessment. However, one data quality summary for groundwater samples collected in May 2010 (ARI Analytical Data Quality Review for the Midway Groundwater Monitoring Event 57; ARI 2010) was available and was reviewed to assess overall data quality (including accuracy, precision, and sensitivity of the sampling results).

Based on the existing information, the following determinations were made regarding the available groundwater monitoring data:

- Although the Midway Landfill Monitoring Plan (Parametrix 2000) and all original laboratory reports and data quality summaries for the annual groundwater sampling events from 2010-2014 were not available at the time of this assessment, these documents were previously approved by Ecology, and therefore, it was assumed that groundwater samples were likely collected and analyzed by reliable and acceptable methods.
- The groundwater data were collected within the last ten years and although there are more recent data (2015-2019), it is unlikely that conditions at the landfill have changed significantly during this time period. Therefore, it was determined that the data are likely to be representative of current site conditions.
- Original analytical laboratory reports were not available at the time of this assessment for data collected in 2011 through 2014, and as a result, reporting limits for those years were not available for comparison with applicable screening levels. However, the original laboratory results for the 2010 groundwater monitoring event were available for review and original laboratory reports and data quality summaries for 2011-2014 groundwater sampling events were previously approved by Ecology. Based on this information, it was assumed that the laboratory reporting limits are sufficiently low for comparison with any applicable screening levels.
- Results for 11 wells that were sampled annually from 2010 through 2014 were available for this assessment. This number of sampling locations and frequency of sampling events were sufficient to assess spatial and temporal variability for groundwater underlying and within the vicinity of the landfill. However, as discussed in Section 3.2.2, results for five wells that were within or just outside the landfill boundaries were considered for this HHRA and two of these wells had not been sampled in several years because they were dry. While this reduced number of sample locations within the landfill footprint limits the assessment of spatial variability for groundwater results, it

has been determined that the number of sample locations and sample events were sufficient to assess the spatial and temporal variability of the results.

Based on the determinations noted above, the 2010-2014 groundwater results are considered to be of sufficient quality and reliability for use in this HHRA. These groundwater data are summarized in Section 3.2.2 and presented for comparison to applicable screening levels in Section 4.2.1.

3.2.2 Groundwater Data Summary

Of the 11 wells sampled as part of the performance and compliance groundwater monitoring programs at the Midway Landfill, the following wells were identified as being located within or just outside of the landfill boundaries (see Figure 2-10 from the Midway Landfill Groundwater Monitoring Status Report 2010-2014 in Appendix A of this report):

- MW-7A is one of three wells located in the UGA and is downgradient and near the southern boundary of the Midway Landfill. MW-7A has not been sampled since 1992 because the well has been dry.
- MW-7B is one of seven wells located in the SA and is downgradient and near the southern boundary of the Midway Landfill. MW-7B was added to the monitoring program beginning in 2011 based on the recommendations of the Second Five-Year Review (USEPA 2015a).
- MW-14B is one of five downgradient wells located in the SGA and is near the eastern boundary of the landfill.
- MW-20A is one of seven wells located in the SA and is downgradient and located just west of the landfill. This well has shown historical groundwater quality impacts but has not been sampled since 1994 because the well has been dry.
- MW-20B is one of five downgradient wells located in the SGA and is located just west of the landfill.

Groundwater samples are analyzed for field and conventional parameters (temperature, specific conductivity, pH, chloride, and sulfate) and the following compounds: 1,4-dioxane by USEPA Method 8270 (USEPA 1996a), vinyl chloride by USEPA Method 8260-Selective Ion Monitoring (SIM) (USEPA 1996b), VOCs by USEPA Method 8260 (USEPA 1996b), and dissolved iron and dissolved manganese by USEPA Method 6010B (USEPA 1996c). Detected concentrations of COIs found in groundwater samples collected from the wells listed above are summarized in Table 1 for comparison to the applicable screening levels discussed further in Section 4.2.1. The groundwater cleanup levels established in the ROD (USEPA 2000a) are also included in Table 1 for reference and are discussed briefly below.

The ROD established cleanup levels for groundwater and required ongoing monitoring of groundwater by the City until groundwater cleanup standards have been achieved. These cleanup levels are listed below.

- 1,2-dichloroethane- 5.0 micrograms per liter (µg/L) based on the Federal Drinking Water Standard Maximum Contaminant Level (MCL),
- Vinyl chloride- 0.29 µg/L based on the MTCA Method B* Groundwater cleanup level (WAC 173-340-720) with an adjusted cancer risk of 10^{-5}, and
- Manganese- 2.2 milligrams per liter (mg/L) based on the MTCA Method B* Groundwater cleanup level.

**MTCA Method B cleanup levels are for unrestricted site uses.*

In 2011, 1,4-dioxane was added to the list of parameters for the routinely monitored wells and a special sampling event was conducted in 2012 for 1,4-dioxane in five additional wells to investigate its extent upgradient of the landfill (Parametrix 2015). Although, no cleanup level was established for 1,4-Dioxane in the ROD, detected concentrations are compared to the MTCA Method B Groundwater cleanup level.

1,2-dichloroethane was not detected in any of the wells located within or just outside of the landfill boundaries during the 2010-2014 sampling rounds.

Vinyl chloride exceeded the ROD cleanup level (0.29 µg/L) in the SA in MW-7B during the 2011-2013 sampling rounds; in the SGA in MW-14B during the 2010-2013 sampling rounds; and in MW-20B during 2013-2014 sampling rounds. In 2014, wells MW-7B and MW-14B had dropped below the cleanup level. In general, the levels of vinyl chloride in all wells located downgradient from the Midway Landfill are declining (USEPA 2015a).

Manganese exceeded the ROD cleanup level in the SA in MW-7B during the 2011-2014 sampling rounds and in the SGA in MW-20B during the 2010-2014 sampling rounds. Manganese continues to decrease in these two wells (USEPA 2015a).

1,4-Dioxane exceeded the MTCA Method B Groundwater cleanup level in the SA in MW-7B during the 2012 sampling round and in the SGA in MW-14B and MW-20B during the 2010-2014 sampling rounds (MW-20B was not sampled in 2010). 1,4-Dioxane concentrations are generally decreasing; however, the levels in the SGA are up to 80 times the MTCA Method B Groundwater cleanup level (USEPA 2015a).

3.2.3 Landfill Gas Data Review

3.2.3.1 Methane Sampling Results (2015-2019)

Landfill gas monitoring has been conducted at the landfill on a regular basis beginning in 1984. Landfill gas is collected from the landfill extraction wells and flares by SPU and analyzed for combustible gas (primarily methane), oxygen, carbon dioxide, temperature, static pressure, and other parameters. SPU provided monthly gas monitoring results for 106 sample locations collected between January 2015 and August 2019 for review as part of this assessment. The sampling and analysis methods for landfill gas (methane) are outlined in the approved Midway Landfill Monitoring Plan (Parametrix 2000). However, as mentioned previously, the Midway Landfill Monitoring Plan (Parametrix 2000) was not available for review and limited-to-no information was available regarding sample locations, frequencies, sample protocols, analytical methods, or data quality at the time of this assessment.

Based on the existing information, the following determinations were made regarding the available landfill gas (methane) monitoring data:

- Although the Midway Landfill Monitoring Plan (Parametrix 2000) was not available for review, it was previously approved by Ecology, and therefore, it was assumed that landfill gas samples were likely collected and analyzed by reliable and acceptable methods.
- Methane gas samples were collected on a monthly basis over the last six years and are considered representative of current site conditions.
- Original analytical laboratory reports and supporting data quality summaries were not available at the time of this assessment and as a result, reporting limits were not available for comparison with any applicable screening levels.
- Methane gas samples were collected from 106 locations on a monthly basis over the last six years. This number of sampling locations and frequency of sampling events are sufficient to assess spatial and temporal variability for methane concentrations in landfill gas.

Based on the determinations noted above, the available landfill gas results for methane are considered to be of sufficient quality and reliability for use in this HHRA. These methane data are summarized in Section 3.2.4 and shown in Tables 2 and 3.

3.2.3.2 VOC and Inorganic Gas Sampling Results (1988 and 1992)

Two available sources of data on the composition of subsurface gas in the vicinity of the Midway Landfill were identified during document review for this HHRA. These sources include a gas characterization study completed in 1988 as part of the RI and a source emission evaluation completed in 1992 to quantify gas flare emission levels at the Midway Landfill.

The 1988 gas characterization study was included in its entirety in Appendix E of the Landfill Gas Technical Report (Parametrix 1988b), which at the time of this assessment was not available for review. However, the Landfill Gas Technical Report is summarized in Section 6.4 of the RI (Parametrix 1988a), which was available for review at the time of this assessment.

According to the RI summary (Parametrix 1988a), one objective of the gas characterization study was to characterize the chemical composition of subsurface gas in the vicinity of and within the landfill. As part of the gas characterization study, gas from individual onsite gas extraction wells was sampled and analyzed for compounds known to be present at specific locations deep within the landfill. In addition, flare inlet gas, representing the combined gas extracted from the numerous individual onsite gas extraction wells, was also characterized to provide a description of the average composition of gas extracted from the landfill (Parametrix 1988a).

Gas samples were collected in Tedlar bags from onsite gas extraction wells and pre-combustion flare gas (flare inlet gas) and analyzed for HSL VOCs by Analytical Technologies, Inc. using gas chromatography/mass spectrometry (GC/MS) in accordance with USEPA Method 624 guidance (Parametrix 1988a).

Concentrations of VOCs detected in subsurface and flare inlet gas during the 1988 gas characterization study were presented in the RI in summary form (mean and/or maximum concentrations) in Table 6-1 and Table 8-1 of the RI (Parametrix 1988a). These data are summarized in Section 3.2.4 and shown in Tables 4 and 5a of this report. The inorganic gases, hydrogen sulfide and carbon monoxide, were also detected in onsite subsurface gas in the low ppm range (Parametrix 1988a). Hydrogen sulfide concentrations reported in Table 7-6 the RI are shown in Table 5b. Carbon monoxide results were not reported (Parametrix 1988a).

The 1992 source emission evaluation, conducted by Am Test-Air Quality Inc. to quantify gas combustor emission levels at the Midway Landfill, includes measured concentrations of VOCs found in pre-combustion flare gas (flare inlet gas) and post-incineration emissions. Subsurface gas extracted from the landfill was sampled during three runs at the inlet and the outlet of one of four landfill gas combustors in order to determine the inlet and outlet emission concentrations, emission rates, and the destruction efficiencies for VOCs in landfill gas. The inlet and outlet gas at Flare #3 were measured to quantify velocity, temperature, and moisture and concentrations of carbon dioxide, oxygen, carbon monoxide, hydrochloric acid, sulfur dioxide, nitrogen oxides, and VOCs. Gas samples were collected at the inlet and outlet of Flare #3 and analyzed for VOCs by Coast-to-Coast Analytical Services in accordance with Compendium Method TO-14 (USEPA 1999) (Am Test-Air Quality Inc. 1992).

The laboratory reported VOCs in micrograms per cubic meter (µg/m^3) were converted in the source emission evaluation (Am Test-Air Quality Inc. 1992) to emission rate units of milligrams per minute (mg/min) for use in the calculation of destruction efficiencies. The emission rate results for each of the three runs at the inlet and outlet of Flare #3 were presented in summary tables on pages 12 (inlet) and 13 (outlet) of the source emission evaluation report (Am Test-Air Quality Inc. 1992). These data are summarized in Section 3.2.4 and shown in Table 6 of this report. A copy of the original laboratory report was included as Appendix B of the source emission evaluation (Am Test-Air Quality Inc. 1992); however, this appendix was not available at the time of this assessment. Carbon monoxide was not detected in flare inlet gas samples collected during the 1992 source emission evaluation.

Based on the existing information, the following determinations were made regarding the available landfill gas (VOCs and inorganic gases) data:

- Documentation detailing the sampling and analysis methods for the landfill gas characterization study (Appendix E of the Landfill Gas Technical Report; Parametrix 1988b) was not available at the time of this assessment. However, the landfill gas characterization study was conducted as part of the RI (under regulatory oversight) and, therefore, the samples were likely collected and analyzed by reliable and acceptable methods.
- The sampling and analysis methods for the source emission evaluation conducted in 1992 were described in Section 5.0 Sampling and Analysis Procedures of the report; however, at the time of this assessment, only Sections 1.0 through 3.0 of the report were available for review and the following sections and appendices were not available; Methodology References (Section 4.0), Sampling and Analysis Procedures (Section 5.0), Calculation Results (Section 6.0), Quality Assurance Plan (Section 7.0), and Laboratory Analysis Results (Appendix B). In addition, it is not clear if the sampling was collected under regulatory oversight. Therefore, a determination could not be made regarding the reliability and acceptability of the methods used for the 1992 source emission evaluation.
- VOC and inorganic gas data from the 1988 landfill gas characterization study and the 1992 source emission evaluation were collected more than 25 years ago and are not expected to be representative of current site conditions.
- The original analytical laboratory data and supporting data quality summaries were not available for the 1988 landfill gas characterization study and the 1992 source emission evaluation at the time of this assessment and as a result, reporting limits were not available for comparison with applicable screening levels.
- It is not clear how many locations were sampled and how many sample events were conducted as part of the 1988 landfill gas characterization study because these details were not provided in the RI summary and Appendix E of the Landfill Gas Technical Report was not available at the time of this assessment. In addition, VOC results were presented in the RI in summary form (mean and/or maximum concentrations only) with no notation of the number of samples collected (see Tables 6-1 and 8-1 of the RI). Therefore, it is not known if the number of sample locations or frequency of sample events were sufficient to assess spatial and temporal variability for VOCs or inorganic

gas concentrations in landfill gas. Hydrogen sulfide results for only two samples collected from the north and south flare inlet were presented in the RI.

- During the 1992 source emission evaluation, three gas samples were collected from one flare inlet and one flare outlet each during a single sample event (February 7, 1992). Additional samples were collected November 7 and 8, 1991, but were not presented in the source emission evaluation after data from this sampling event indicated that there had been a leak in the inlet sampling system. The limited number of sample locations (one flare inlet) and frequency of sample events (one day) are not sufficient to assess spatial and temporal variability for VOC concentrations in landfill gas.

Based on the determinations noted above, the available landfill gas results for VOCs and inorganic gases are not considered to be of sufficient quality and reliability for use in this HHRA and should not be compared to risk-based screening levels. However, to document the available data and for informational purposes, these data are summarized in Section 3.2.4 and Tables 4, 5a, 5b and 6 of this report. When reviewing these data, it is important to note that landfill gas samples collected from the landfill gas extraction system do not provide a representative measure of the COI concentrations that workers may be exposed to at the OMF South for the following reasons: 1) these gas samples were collected under vacuum conditions from varying depths within the landfill and therefore are not likely to be representative of gases that may be escaping the landfill cap, and 2) these gas samples are not likely to be representative of gas concentrations that would be found near the surface due to differences in attenuation prior to sample collection.

3.2.4 Landfill Gas Data Summary

3.2.4.1 Methane Sampling Results (2015-2019)

Monthly methane sample results for January 2015 through August 2019 were provided by SPU for this HHRA. These results included methane concentrations for 106 locations within the landfill gas extraction system (e.g., extraction wells, vacuum manifolds, etc.). Raw data were provided in excel format with limited information on the well locations. However, to confirm their onsite location, well identification numbers were compared to onsite extraction wells and vacuum manifold shown on Figure 8 of the Third Five-Year Review (USEPA 2015a) and included in Appendix A of this report. Wells labeled as 1, 50, 52, MAN, MAN-N, and MAN-S could not be located, but are included in the methane summary tables (Tables 2 and 3). All other wells were confirmed as onsite based on Figure 8 of the Third Five-Year Review (USEPA 2015a).

No applicable toxicity- or risk-based screening levels are available for comparison to methane concentrations detected in landfill gas. However, state regulations (WAC 173-304-460) establish that methane concentrations at a landfill shall not exceed the following:

- 25% of the lower explosive limit (LEL) in facility structures (excluding gas control or recovery system components);
- 100% of the LEL at the property boundary or beyond; and
- 100 ppm by volume of hydrocarbons (expressed as methane) in offsite structures.

Available methane data were summarized by sample location (e.g., onsite extraction well or vacuum manifold) and by year in Table 2 and Table 3. Methane concentrations above the LEL of 5% by volume were found at 75 of the onsite locations (e.g., at least one or more samples collected from these locations between January 2015 and August 2019 were greater than the LEL). The majority (>50%) of all samples collected between January 2015 and August 2019 exceed the LEL (Table 3). Methane concentrations from onsite locations sampled between January 2019 and August 2019 range from 0 to 27.9% with an average concentration of 7.3% (Table 3).

According to the Third Five-Year Review for the Midway Landfill Superfund Site, methane concentrations above the LEL have been detected outside the landfill boundary at one probe location (AM) from 2010 through 2014 (USEPA 2015a). Methane concentrations are highest in the shallow completion of the AM probe, screened from 25 to 40 feet bgs (USEPA 2015a). The AM gas probe is located at the northeast corner of the landfill and is outside the influence of the current gas extraction system (USEPA 2015a) (see Figure 9 of the Third Five-Year Review in Appendix A of this report). No additional offsite probes have shown detected concentrations of methane above the LEL from 2010 through 2014.

3.2.4.2 VOC and Inorganic Gas Sampling Results (1988 and 1992)

A wide variety of substances, including 23 HSL VOCs, were found in subsurface gas collected from the onsite gas extraction wells and flare manifolds during the gas characterization study and source emissions evaluation. The RI noted that ethylbenzene, vinyl chloride, total xylenes, toluene, and benzene were found most frequently and in the highest concentrations in onsite subsurface gas (Parametrix 1988a) and the mean and maximum concentrations of these select compounds were presented in Table 6-1 of the RI. Maximum observed concentrations of additional VOCs detected in onsite subsurface gas and flare inlet gas samples were presented in Table 8-1 of the RI (Parametrix 1988a). These results were presented in parts per billion (ppb) in the RI and were converted to $\mu g/m^3$, as shown in Tables 4 and 5a. Hydrogen sulfide concentrations reported in Table 7-6 of the RI are shown in Table 5b.

Fifteen VOCs were detected in inlet gas (Flare #3) during the 1992 source emission evaluation. The original laboratory analysis reported VOCs in concentration units of $\mu g/m^3$; however, these concentration units were converted to emission rate units of mg/min for use in calculating destruction efficiencies for the evaluation. The original laboratory analysis was not available at the time of this assessment. Therefore, the emission rate results presented in the report (mg/min) were converted back to µg/m^3 using the air flow rates (dry standard cubic feet per minute) for the inlet of Flare #3 provided in the summary table on page 8 of the source emissions evaluation. These results are shown in Table 6 of this report.

Because these VOC and inorganic gas sampling results (1988 and 1992) are not of sufficient quality and reliability and are not considered to be representative of current site conditions, a quantitative comparison between detected concentrations and applicable screening levels will not be made. However, regulatory screening levels for sub-slab, deep soil, and near source soil gas for occupational exposures are included in Table 7 of this report for reference.

3.3 Potential Data Gaps

Based on an examination of available environmental data and supporting documents, the groundwater and methane datasets are considered to be of sufficient quality and reliability to support a quantitative comparison to risk-based screening levels as part of this HHRA.

However, additional sampling is needed to develop a sufficient and reliable dataset to characterize site conditions and human health risks associated with potential exposures to COIs in landfill gas. Future sampling of landfill gas constituents should be conducted following an approach that generates the appropriate environmental data needed to characterize occupational exposures and evaluate potential health risks at the OMF South. Some representative measures of occupational exposure to VOCs and inorganic gases in landfill gas may include post-construction sub-slab soil gas concentrations and/or indoor air concentrations.

4.0 Exposure Assessment

The first step in an exposure assessment is the development of a Conceptual Site Model (CSM). The CSM describes the physical characteristics of the site, site-specific exposure scenarios, potential exposure pathways (or routes of exposure), and potentially exposed populations. Following development of the CSM, site COPCs are identified by comparing concentrations of COIs found in groundwater and landfill gas to risk-based screening levels.

Once site COPCs are identified through this screening process, the magnitude, frequency, and duration of exposures at the site can then be quantified based on COPC concentrations and chemical- and pathway-specific intake parameters.

This section presents the CSM, a quantitative comparison of exposure concentrations to risk-based screening levels, and a discussion of site COPCs.

4.1 Conceptual Site Model

The CSM for the Midway Landfill describes potential chemical sources, release mechanisms, environmental transport processes, exposure scenarios, potential routes of exposure, and potentially exposed populations. The primary purpose of the CSM is to describe pathways by which human receptors may be exposed to COIs at a site. According to the USEPA (1989), a complete exposure pathway consists of four necessary elements: 1) a source and mechanism of chemical release to the environment, 2) an environmental transport medium for a released chemical, 3) a point of potential contact with the impacted medium (referred to as the exposure point), and 4) an exposure route (e.g., groundwater ingestion, vapor intrusion) at the exposure point.

The CSM, based on available information, is shown in Figure 1 and primary sources of landfill COIs, human receptors, and potentially complete routes of exposure are discussed below.

4.1.1 Primary Sources

The majority of chemical impacts to groundwater and subsurface gas at the Midway Landfill result from landfill waste. However, site investigations indicated that some chemicals found in onsite groundwater and subsurface gas were also found in upgradient groundwater monitoring wells and therefore may be from unidentified, upgradient sources (USEPA 2015a).

As discussed in Section 2.2, the Midway Landfill was used as a landfill for demolition materials, wood waste, and other slowly decomposing materials (USEPA 2015a). Records from the early 1980s indicate that paint sludge, dyes, preservatives for decorative plants, alkaline wastes, oily sludge, waste coolant, truck steam cleaning wastes, and some oily wastes were deposited at the site (Parametrix 1988a). In addition, approximately two million gallons of bulk industrial liquids from a single source were placed in the landfill (USEPA 2015a). However, the nature and type of industrial liquids disposed of in the Midway Landfill is not known.

According to the RI, an estimated three million cubic yards of solid waste were deposited in the Midway Landfill (Parametrix 1988a). Landfill gas is a byproduct of decomposition of organic materials in landfills. Landfill gas is composed mainly of methane and carbon dioxide. However, VOCs (such as benzene and vinyl chloride) can also be found in landfill gas.

During the RI, onsite landfill gas was found to contain numerous USEPA HSL VOCs with ethylbenzene, vinyl chloride, total xylenes, toluene, and benzene found most frequently and in the highest concentrations onsite. Hydrogen sulfide and carbon monoxide were also detected in onsite landfill gas samples (Parametrix 1988a).

The RI identified a number of HSL compounds in groundwater and the ROD established groundwater cleanup levels for manganese, 1,2-dichloroethane, and vinyl chloride based on the protection of downgradient drinking water. The most recent groundwater quality results from 2010-2014 (Parametrix 2015) showed the following exceedances in groundwater wells in the vicinity of the Midway Landfill:

- One downgradient well in the SGA exceeded the 1,2-dichloroethane cleanup level in 2013.
- One upgradient well in the SA and three downgradient wells in the SGA exceeded the vinyl chloride cleanup level during the 2010-2014 sampling rounds with one upgradient well in the SA and one downgradient well in the SGA dropping below the vinyl chloride cleanup level in 2014.
- Two downgradient wells (one in the SA and one in the SGA) exceeded the manganese cleanup level during the 2010-2014 sampling rounds.
- 1,1-dichloroethene, tetrachloroethene, and trichloroethene have consistently been detected in two upgradient wells in the SA at concentrations greater than MTCA Method B Groundwater cleanup levels. However, high tetrachloroethene concentrations (ranging from 110-130 µg/L) in one of the upgradient wells indicates the presence of an upgradient source of this contaminant.
- 1,4-Dioxane has been detected in two upgradient wells and one downgradient well in the SA at concentrations greater than the MTCA Method B Groundwater cleanup level. All downgradient wells in the SGA have exceedances of 1,4-dioxane in all rounds of sampling from 2010-2014. The boundary of the 1,4-dioxane plume is unknown at this time, and additional characterization is needed to determine its extent (USEPA 2015a).

4.1.2 Fate and Transport

The primary release mechanisms that affect the fate and transport of COIs released from waste contained in the Midway Landfill include leaching from waste to underlying groundwater and the migration of landfill gas into and through subsurface soil (see Figure 1).

Secondary release mechanisms include the volatilization of COIs from groundwater into subsurface soil and the transport of subsurface soil gas through the subsurface or through the landfill cover. COIs may also migrate through underlying groundwater.

Advection and dispersion in groundwater, sorption to the soil, and natural degradation processes also play a role in the fate and transport of each COI depending on its individual chemical and physical properties. In addition, the properties of soil and the dynamics of groundwater flow also impact contaminant fate and transport. Once in groundwater, dissolved COIs may be transported by diffusion and advection in groundwater. In general, the potential for a chemical to migrate in groundwater increases as a function of chemical solubility. Dispersion, retardation, and biodegradation act to reduce dissolved concentrations of COIs in groundwater downgradient of the source area.

Some COIs found in waste, soil, soil gas, or groundwater may volatilize into soil pore spaces and migrate via diffusion and advection through the soil into indoor and/or outdoor air. Diffusive transport generally moves in the direction of lower soil gas concentrations while advective transport occurs in the direction of lower air pressure. Advection can occur near buildings due to differences in temperatures between the building and the subsurface environment or the operation of heating and cooling systems and fans that create pressure differentials and influence soil gas entry. Advection of soil gas may also occur due to fluctuations in barometric pressure. In addition, landfills where methane is generated in sufficient quantities may induce advective transport. Overall, soil gas concentrations decrease as the volatile chemicals move from the source through subsurface soil and into indoor or outdoor air (USEPA 2015b).

The infiltration of water into the landfill waste and subsequent leaching to groundwater and the migration of landfill gas through the subsurface to indoor and ambient air is currently controlled by the gas extraction system and the landfill cap. The cap provides a barrier which, along with the gas extraction system, reduces the migration of volatile compounds found in landfill gas and groundwater to the surface where they may enter onsite buildings and/or outdoor air. Migration of volatile compounds through the landfill cover is possible if the gas extraction and cover system were compromised.

If buildings are located directly over an area where the landfill cap has been compromised, it is possible that vapors may enter indoor air by penetrating cracks in a building floor, slab, or foundation, or via mechanical systems. Once in outdoor air, mixing with ambient air is expected to reduce COI concentrations substantially (USEPA 2015b).

4.1.3 Exposure Scenarios

The Midway Landfill will be used for occupational purposes if it is selected as the location of the future OMF South. As a result, various workers (not residents) will have the greatest potential to contact impacted soil gas, groundwater, or air. These workers include long-term Onsite Office, Maintenance Shop, and Yard Workers and short-term Construction Workers.

The following potential exposure scenarios were identified for OMF South personnel at the Midway Landfill. The exposure scenarios described below are not exhaustive but rather are intended to represent exposure profiles for broad occupational categories for those personnel with similar work environments, activities, and exertion levels. Potential occupational routes of exposure to COIs found in landfill waste, gas, and groundwater are described in the CSM (Figure 1) and discussed in Section 4.1.4.

4.1.3.1 Onsite Office Worker

The Onsite Office Worker spends most, if not all of the workday indoors conducting relatively sedentary activities (e.g., desk work, meetings). This exposure scenario assumes that the Onsite Office Worker is a long-term, full-time employee at the OMF South. The Onsite Office Worker is assumed to work at the OMF South for 8 hours a day, 5 days a week for 30 years.

4.1.3.2 Maintenance Shop Worker

The Maintenance Shop Worker spends most, if not all of the workday conducting maintenance activities inside a shop that can be opened to the outdoors during good weather. This exposure scenario assumes that the Maintenance Shop Worker is a long-term, full-time employee at the OMF South who spends a portion of the year working in an enclosed indoor environment and within depressed maintenance pits and a portion of the year working in an environment where s/he is exposed to a mix of indoor and outdoor air. The Maintenance Shop Worker is assumed to work at the OMF South for 8 hours a day, 5 days a week for 30 years.

4.1.3.3 Yard Worker

The Yard Worker spends most, if not all of the workday conducting relatively vigorous work activities outdoors. This exposure scenario assumes that the Yard Worker is a long-term, full-time employee at the OMF South. The Yard Worker is assumed to work at the OMF South for 8 hours a day, 5 days a week for 30 years.

4.1.3.4 Construction Worker

The Construction Worker spends most, if not all of the workday conducting vigorous construction activities outdoors. This exposure scenario assumes that the Construction Worker is a short-term, full-time employee at the OMF South. The Construction Worker may periodically enter onsite utility trenches and underground stormwater vaults for repair and maintenance. The Construction Worker is assumed to work at the OMF South for 10 hours a day, 5 days a week for 6 years.

4.1.4 Potential Routes of Exposure

Based on the knowledge of the current conditions at the Midway Landfill and possible future site uses, the following potential occupational routes of exposure to COIs in landfill waste, gas, and groundwater were identified and evaluated (see Figure 1):

- Inhalation of Indoor Air
- Inhalation of Air in Subsurface Confined Spaces (e.g., utility trenches and vaults),
- Inhalation of Outdoor Air,
- Groundwater Ingestion, and
- Direct Contact with Waste and Contaminated Soil.

These potential routes of exposure are based on the assumptions that construction of the OMF South may result in future site conditions that could allow for vapor intrusion from subsurface gas and underlying groundwater to indoor air (see the description of Concept 3 in Section 2.4.3).

4.1.4.1 Inhalation of Indoor Air

It is assumed that onsite workers could have indirect exposure to COIs in vapors from subsurface soil gas and/or groundwater due to vapor intrusion into indoor or confined spaces (including depressed maintenance pits) and subsequent inhalation of indoor air.

According to the USEPA (2015b), the vapor intrusion pathway is considered complete when the following conditions are met:

1) A subsurface source of vapor-forming chemicals is present underneath or near buildings;
2) Vapors form and have a route along which to migrate toward the building;
3) Openings exist for vapors to enter the building and driving ‘forces’ (e.g., air pressure differences between the building and the subsurface environment) exist to draw the vapors from the subsurface through the openings into the buildings;
4) One or more vapor-forming chemicals comprising the subsurface vapor sources are found to be present in the indoor environment; and
5) The buildings are occupied by one or more individuals when the vapor-forming chemicals are present indoors.

Although the migration of landfill gas is currently controlled by the gas extraction system and the landfill cap and no buildings are located at the landfill at this time, future buildings could be constructed in such a way that vapors from subsurface soil gas or groundwater could breach the cap and enter indoor air through cracks in a building's foundation where they could then be inhaled by workers. This route of exposure is likely to be complete if adequate engineered protections including a functioning gas extraction system and landfill cap are not in place to prevent vapor intrusion. This is a potentially complete route of exposure for Onsite Office and Maintenance Shop Workers.

4.1.4.2 Inhalation of Air in Confined Spaces

OMF South workers could have indirect exposure to volatile COIs in subsurface soil gas and groundwater via vapor migration through the subsurface to confined spaces such as utility trenches and stormwater vaults where they could then be inhaled by workers. This route of exposure is likely to be complete if adequate engineered protections, (e.g., a functioning gas extraction system and landfill cap) are not in place to prevent vapor migration and if worker health and safety protocols for confined spaces are not followed. This is a potentially complete route of exposure for Construction Workers.

4.1.4.3 Inhalation of Outdoor Air

Another pathway by which workers could have indirect exposure to volatile COIs in subsurface soil gas and groundwater is vapor migration through the landfill cap into outdoor air where they could then be inhaled by workers. This route of exposure is likely to be complete if adequate engineered protections (e.g., a functioning gas extraction system and landfill cap) are not in place to prevent vapor migration to the surface. This is a potentially complete route of exposure for Maintenance Shop, Yard, and Construction Workers.

4.1.4.4 Groundwater Ingestion

Currently, no one is known to be drinking groundwater from any aquifer within almost a mile of the landfill (USEPA 2015a) and there are no water supply wells at the landfill. Further, state regulations (WAC 173-160-171) do not allow any new private drinking water wells within 1,000 feet of a solid waste landfill or 100 feet of all other sources or potential sources of contamination and Ecology must be notified prior to the construction of any well (USEPA 2015a). Per the NCP, the Midway Landfill is considered a waste management area and thus is not considered a future drinking water source by the USEPA (USEPA 2015a). As a result, this route of exposure is considered to be incomplete for all occupational exposure scenarios described above.

4.1.4.5 Direct Contact with Waste and Contaminated Soil

Landfill waste and contaminated soil are currently covered by the landfill cap which prevents workers from directly contacting subsurface contamination. However, it is assumed that this landfill cap will be temporarily removed to allow for excavation into the underlying waste and soils during construction of the OMF South. Without the use of proper personal protective equipment (PPE) and site controls, Construction Workers may be exposed to contaminants through incidental inhalation, dermal exposure, and incidental ingestion of exposed waste and contaminated soil during construction and excavation activities. This is a potentially complete route of exposure for Construction Workers.

4.2 Selection of COPCs for the HHRA

To focus the HHRA on COIs with the potential to cause health risks to workers who may come in contact with them through a potentially complete or complete exposure route, the list of chemicals detected at the Midway Landfill was evaluated and reduced. COPCs have been selected using criteria recommended by the USEPA (1989) and best scientific judgment. Chemicals were selected primarily on the basis of measured concentrations and inherent toxicity.

COPCs were selected by comparing the maximum detected concentration to applicable risk-based screening levels. These risk-based screening levels are media-specific concentrations derived from conservative exposure assumptions and available toxicity values.

Screening values are compared to chemical concentrations in site media to qualitatively assess risk to future OMF South workers and to determine if COPC concentrations warrant additional investigation and/or a more detailed, site-specific risk assessment before adequate risk management decisions can be made.

Groundwater concentrations were compared to vapor intrusion screening levels for occupational exposure scenarios (MTCA Method C Groundwater Vapor Intrusion Screening Level; Ecology 2018a and 2018b; WAC 173-340-750) and USEPA Worker Air Vapor Intrusion Screening Levels (VISLs) for Groundwater (USEPA 2018a) (Table 1).

As mentioned earlier, no risk-based screening levels for methane are available for comparison in the HHRA due to a lack of toxicological effects (see the toxicological profile for methane in Section 5.1.2). However, methane is highly flammable, can explode at concentrations between 5% (LEL) and 15% (upper explosive limit), and is a simple asphyxiant that can cause death at concentrations much higher than the explosive range (5-15%). Non-toxicological hazards associated with methane are discussed in more detail in Section 5.1.2 and Section 7.

During data evaluation, it was determined that available landfill gas results for VOCs and inorganic gases are not of sufficient quality and reliability for use in this HHRA and do not represent current conditions at the Midway Landfill. Therefore, VOCs and inorganic gases found in landfill gas are not considered for quantitative risk assessment and are not compared to applicable screening levels. Instead, the data are presented in Tables 4, 5a, and 6 and the toxicities of select VOCs (e.g., those with historically high concentrations) are discussed in Section 5.1.1 for informational purposes only. Regulatory screening levels for sub-slab, deep soil, and near source soil gas for occupational exposures are also presented in Table 7 for reference.

Screening levels for groundwater vapor intrusion and sub-slab, deep soil, and near source gas, along with the exposure assumptions and target risk levels used to derive these screening levels, are discussed in detail in Section 4.2.1.

4.2.1 Screening Levels

Applicable risk-based screening levels were selected for comparison with COI concentrations based on the future occupational use of the site, the occupational (worker) exposure scenarios, and the potentially completed routes of exposure identified in Sections 4.1.3 and 4.1.4. These screening levels were reviewed to verify that they were sufficiently protective of the occupational exposures expected to occur at the OMF South. The basis for the risk-based screening levels selected for comparison (or reference, in the case of subsurface soil gas) is described below.

In order to derive groundwater vapor intrusion and soil gas vapor intrusion screening levels that are protective of indoor air, acceptable indoor air concentrations must first be established. These acceptable air concentrations (USEPA Indoor Worker VISL [USEPA 2018a] and MTCA Method C Indoor Air cleanup levels [WAC 173-340-750] for facilities qualifying as industrial properties under WAC 173-340-745 and for utility vaults and manholes [WAC 173-340-706]) are based on exposure assumptions that are highly protective in nature and are derived using the assumptions and equations shown in Figures 2 and 3.

Indoor air screening levels are calculated using conservative assumptions regarding inhalation rate, exposure duration, and other exposure factors for occupational workers. For example, the USEPA Indoor Worker VISLs have been developed assuming workers have chronic exposure to impacted indoor air over most of their careers (i.e., 250 days per year, 8 hours a day for 25 years for carcinogens and non-carcinogens) and the MTCA Method C Indoor Air cleanup levels for occupational scenarios have been developed with similar conservative exposure assumptions (i.e., 365 days per year, 24 hours per day for 30 years for carcinogens and 365 days per year, 24 hours per day for 6 years for non-carcinogens) (See Figures 2 and 3 for these screening level equations and exposure parameters).

The target risk levels used by the USEPA when developing these screening levels are the same as those used in the MTCA Method C Indoor Air cleanup level equations (see Figures 2 and 3).

Target risk levels for carcinogens is one in a one hundred thousand (10^{-5}) excess cancer risk over a lifetime or the probability that a lifetime exposure to a substance increases a person's chance of developing cancer by one chance in one hundred thousand or less. For the non-carcinogens, the target risk is a hazard quotient of one. A hazard quotient is the ratio of the potential exposure to a substance (or dose) and the level at which no adverse effects are expected. If the hazard quotient is calculated to be greater than one, then adverse health effects are possible.

Both the USEPA Indoor Worker VISL and MTCA Method C Indoor Air cleanup level for a carcinogenic chemical are expressed as a concentration associated with a one in a one hundred thousand (10^{-5}) excess cancer risk over a lifetime. For a non-carcinogen, these screening levels are expressed as the concentration associated with a hazard quotient of one.

Once acceptable risk-based indoor air concentrations have been established, screening levels for Soil Gas and Groundwater Vapor Intrusion are derived by applying USEPA-recommended generic vapor attenuation factors that are protective of worst case vapor intrusion scenarios. Generic vapor attenuation factors and equations for groundwater, and sub-slab, near source, and deep soil gas are shown in Figures 4 and 5.

Soil Gas and Groundwater Vapor Intrusion screening levels that are protective of acceptable indoor air concentrations are also expected to be protective of acceptable outdoor air concentrations due to the substantial reduction of COIs in outdoor air concentrations when mixed with ambient air. However, these screening levels are not expected to be protective of air concentrations in underground confined spaces.

4.2.2 Contaminants of Potential Concern

Maximum concentrations of those COIs detected in groundwater samples from 2010 through 2014 were compared to occupational screening levels for vapor intrusion (e.g., MTCA Method C Groundwater Vapor Intrusion screening levels or the USEPA Worker Air VISLs for Groundwater) in Table 1. Because the groundwater ingestion pathway is not currently complete and will not be complete in the future, groundwater results were not compared to screening levels for groundwater ingestion.

No COIs detected in underlying groundwater at the Midway Landfill exceed the respective MTCA Method C Groundwater Vapor Intrusion Screening Levels or the USEPA Worker Air VISLs for Groundwater (Table 1). As a result, based on the exposure scenarios and potentially complete exposure routes identified in the CSM (Figure 1) and discussed in detail in Section 4.1, no groundwater COPCs were selected for quantitative risk assessment.

As discussed in Section 4.2, due to the absence of representative landfill gas results for VOCs and inorganic gases, no subsurface soil gas COPCs were identified. However, because a number of VOCs in landfill gas were detected relatively frequently and, in some cases, at high concentrations in previous investigations, they have been included in the Toxicity Assessment in

Section 5.1.1 below. A toxicity profile for methane gas is also included in Section 5.1.2 and non-toxicological hazards associated with methane gas are discussed in Section 7.

5.0 Toxicity Assessment

In order to characterize potential carcinogenic and non-carcinogenic risks associated with complete exposure routes, toxicity information for each potential site contaminant is evaluated as part of the toxicity assessment. The recommended hierarchy of toxicological sources for use in human health risk assessment involves three tiers. Tier 1 is the USEPA Integrated Risk Information System (IRIS); the first source of toxicity data. Tier 2 is the USEPA Provisional Peer Reviewed Toxicity Values (PPRTV). Many of the PPRTVs are developed by the USEPA National Center for Environmental Assessment (NCEA). Finally, Tier 3 includes additional USEPA and non-USEPA toxicity sources.

Two general types of health effects are considered in human health risk assessment: cancer effects and adverse non-cancer effects. This distinction is made because the USEPA generally assumes that a dose threshold exists for non-carcinogens, and that adverse health effects are unlikely to occur if humans are exposed to chemical doses below the threshold. No such threshold is generally assumed for carcinogens. Instead, it is assumed that there is a finite probability of developing cancer associated with any exposure to a carcinogen.

As a result, carcinogens and non-carcinogens have separate toxicity criteria. Reference dose or reference concentration values are used to evaluate non-carcinogenic health effects, and slope factors or unit risk factors are used to evaluate carcinogenic health risks. In general, the toxicological effects of a compound are the dominant health effects of the chemical as determined by the USEPA.

5.1 Toxicological Profiles for VOCs in Landfill Gas

Benzene

Benzene is a known human carcinogen for all routes of exposure (inhalation, oral, and dermal) based upon convincing human evidence as well as supporting evidence from animal studies. Epidemiologic studies and case studies provide clear evidence of a causal association between exposure to benzene and acute myelogenous leukemia, which is a cancer of the blood-forming organs, and also suggest evidence for other subtypes of leukemia such as non-Hodgkin’s lymphoma (a cancer that forms in lymphocytes) and multiple myeloma (a cancer that forms in plasma cells) (ATSDR 2007a, 2015a). These human data are supported by animal studies. The experimental animal data add to the argument that exposure to benzene increases the risk of cancer in multiple species at multiple organ sites. Recent evidence supports the viewpoint that there are likely multiple mechanistic pathways leading to cancer and, in particular, to the development of leukemia from exposure to benzene (ATSDR 2007a, 2015a). The oral slope factor[4] for benzene is $1.5\text{x}10^{-2}$ to $5.5\text{x}10^{-2}$ milligrams per kilogram per day^{-1} (mg/kg-day)$^{-1}$ (IRIS 2003a).

Benzene has a low solubility rate and resulting low bioaccumulation in marine life. Benzene is mobile in soil and leaches into groundwater depending on soil type, amount of rainfall, depth of the groundwater, and extent of degradation. It tends to adsorb to aquifer solids and greater soil adsorption was observed with high organic matter content. Benzene is highly volatile and benzene released to the environment partitions mainly to the atmosphere. Biodegradation, principally aerobic, is the most important fate process of benzene in water and benzene can persist in groundwater (ATSDR 2007a).

Chlorobenzene

Chlorobenzene is a colorless liquid with an almond-like odor. The compound does not occur widely in nature, but is manufactured for use as a solvent and is used in the production of other chemicals. Chlorobenzene persists in soil (several months), in air (3.5 days), and water (less than 1 day) (ATSDR 1990).

Chlorobenzene is not classifiable as a human carcinogen based on no human data and inadequate animal data (IRIS 1990a). Occupational exposure occurs primarily through breathing the chemical. Workers exposed to high levels of chlorobenzene complained of headaches, numbness, sleepiness, nausea, and vomiting. However, it is not known if chlorobenzene alone was responsible for these health effects since the workers may have also been exposed to other chemicals at the same time (ATSDR 1990). The reference dose (RfD) is $2\text{x}10^{-2}$ mg/kg-day and affects the liver (IRIS 1990a).

1,4-Dichlorobenzene

Dichlorobenzenes do not occur naturally; chemical companies produce them to make products for home use and other chemicals such as herbicides and plastics. 1,4-Dichlorobenzene, the most important of the three chemicals (1,2-dichlorobenzene, 1,3-dichlorobenzene, and 1,4-dichlorobenzene), is a colorless to white solid. It smells like mothballs and it is one of two chemicals commonly used to make mothballs. 1,4-Dichlorobenzene also is used to make deodorant blocks used in garbage cans and restrooms, and to help control odors in animal-holding facilities. 1,4-Dichlorobenzene has been used as an insecticide on fruit and as an agent to control mold and mildew growth on tobacco seeds, leather, and some fabrics (ATSDR 2006a).

---

[4] An oral slope factor is a measure of a chemical's carcinogenicity. More precisely, it is an estimate of the probability that an individual will develop cancer if orally exposed to a specified amount or dose of the chemical every day for a lifetime.

The U.S. Department of Health and Human Services has determined that 1,4-dichlorobenzene might be a human carcinogen. The International Agency for Research on Cancer (IARC) (an expert group that is part of the World Health Organization) determined that 1,4-dichlorobenzene is possibly carcinogenic to humans (ATSDR 2006a; IRIS 1994). It has a reference concentration (RfC) of $8x10^{-1}$ milligrams per cubic meter (mg/m^3) (IRIS 1994). Humans are exposed to 1,4-dichlorobenzene mainly by breathing vapors from 1,4-dichlorobenzene products. Inhaling the vapor or dusts of 1,2-dichlorobenzene and 1,4-dichlorobenzene at very high concentrations could be very irritating to the eyes and nose and cause burning and tearing of the eyes, coughing, difficult breathing, and an upset stomach. Animal studies also found that 1,4-dichlorobenzene caused effects in the kidneys and blood. Lifetime exposure to 1,4-dichlorobenzene by breathing or eating induced liver cancer in mice.

1,1-Dichloroethane

1,1-Dichloroethane is a colorless oily liquid with a chloroform-like odor and is a chemical used mostly as an intermediate in the manufacture of 1,1,1-trichloroethane. 1,1-Dichloroethane is also used in limited amounts as a solvent for cleaning and degreasing, and in the manufacture of plastic wrap, adhesives, and synthetic fiber (ATSDR 2015b).

Based on no human data and limited evidence of carcinogenicity in animals (rats and mice), 1,1-dichloroethane is a possible human carcinogen. In those studies using high doses of 1,1-dichloroethane in rats and mice, there is an increased incidence of mammary gland adenocarcinomas (cancer of the glandular tissues) and hemangiosarcomas (cancer of the blood vessels) in female rats and an increased incidence of hepatocellular carcinomas (liver cancer) and benign uterine polyps in mice (IRIS 1990b).

Relatively little information is available on the health effects of 1,1-dichloroethane in humans or animals. 1,1-Dichloroethane is in a class of chemicals, called chlorinated aliphatics, which are known to cause central nervous system depression and respiratory tract and dermal irritation when humans are exposed by inhalation to sufficiently high levels. In the past, 1,1-dichloroethane was used as an anesthetic; however, this use was discontinued due to the risk of causing heart rhythm problems (cardiac arrhythmias) in humans at anesthetic doses (approximately 26,000 ppm). A small number of animal studies have examined the toxicity and carcinogenicity of 1,1-dichloroethane; these studies have failed to conclusively identify the critical targets of toxicity (ATSDR 2015b). There is neither a RfD for oral exposure nor a RfC for inhalation exposure (IRIS 1990b).

1,1-Dichloroethane does not degrade quickly in water, but it can evaporate from the water into the air. 1,1-Dichloroethane released to soil surfaces evaporates rapidly to the air. Residual 1,1-dichloroethane remaining on soil surfaces would be available for transport into groundwater, since it is not expected to bind to soil particulates unless the organic content of the soil is high (ATSDR 2015b).

1,2-Dichloroethane

1,2-Dichloroethane is a manufactured chemical that is not found naturally in the environment. It is a clear liquid and has a pleasant smell and sweet taste. The most common use of 1,2-dichloroethane is in the production of vinyl chloride which is used to make a variety of plastic and vinyl products including polyvinyl chloride (PVC) pipes, furniture and automobile upholstery, wall coverings, housewares, and automobile parts. It is also used as a solvent and is added to leaded gasoline to remove lead (ATSDR 2001).

1,2-Dichloroethane is a probable human carcinogen based on sufficient evidence of carcinogenicity in animals. In those studies, several tumor types in rats and mice treated by feeding tube were found and benign cell growths (papillomas) in the lungs of mice were found after they were fed large doses of 1,2-dichloroethane. There are no human data to support this carcinogenic finding (IRIS 1987). People who were accidentally exposed to large amounts of 1,2-dichloroethane in the air or who swallowed 1,2-dichloroethane by accident or on purpose often developed nervous system disorders and liver and kidney disease. Lung effects were also seen after a large amount of 1,2-dichloroethane was inhaled. Studies in laboratory animals also found that breathing or swallowing large amounts of 1,2-dichloroethane produced nervous system disorders, kidney disease, or lung effects. Reduced ability to fight infection was also seen in laboratory animals who breathed or swallowed 1,2-dichloroethane, but it is not known if this also occurs in humans. Longer-term exposure to lower doses also caused kidney disease in animals (ATSDR 2001). The oral slope factor for 1,2-dichloroethane is 9.1×10^{-2} (mg/kg-day)$^{-1}$. Oral RfD and inhalation RfC have not been evaluated (IRIS 1987).

1,2-Dichloroethane evaporates into the air very fast from soil and water. In the air, it breaks down by reacting with other compounds formed by the sunlight. 1,2-Dichloroethane will stay in the air for more than 5 months before it is broken down. It may also be removed from air in rain or snow. Since it stays in the air for a while, the wind may carry it over large distances. In water, 1,2-dichloroethane breaks down very slowly and most of it will evaporate to the air. In soil, 1,2-dichloroethane either evaporates into the air or travels down through soil and enters underground water. Small organisms living in soil and groundwater may transform it into other less harmful compounds, although this happens slowly (ATSDR 2001).

Ethylbenzene

Ethylbenzene is a colorless liquid that smells like gasoline. It moves easily into the air from water and soil. Ethylbenzene in soil can also contaminate groundwater. However, ethylbenzene is not considered highly persistent in the environment. Biodegradation under aerobic conditions and indirect photolysis are important degradation mechanisms for ethylbenzene in soil and water. Volatilization from water and soil surfaces is expected to be an important environmental fate process for ethylbenzene (ATSDR 2010).

Ethylbenzene is not classifiable as to human carcinogenicity due to lack of animal and human studies (IRIS 1988); however, the IARC has determined that long-term exposure to ethylbenzene may cause cancer in humans (ATSDR 2010). Ethylbenzene has an RfD of $1x10^{-1}$ mg/kg-day (IRIS 1988). In humans, exposure to high levels of ethylbenzene in the air for short periods can cause eye and throat irritation. Exposure to higher levels of ethylbenzene in short periods can result in vertigo and dizziness.

1,1,2,2-Tetrachloroethane

1,1,2,2-Tetrachloroethane is a synthetic, colorless, dense liquid that does not burn easily. It has a penetrating, sweet odor similar to chloroform. In the past, it was used in large amounts to produce other chemicals and as an industrial solvent. 1,1,2,2-Tetrachloroethane was also used to separate fats and oils from other substances, to clean and degrease metals, and in paints and pesticides. Although at one time it was used as an insecticide, fumigant, and weed killer, it presently is not registered for any of these purposes. Less toxic chemicals are now available to replace this solvent and large scale commercial production has stopped, although some production still occurs. It is presently used as a chemical intermediate, and information about this use is limited (ATSDR 2008).

1,1,2,2-Tetrachloroethane is likely to be carcinogenic to humans based on animal data (IRIS 2010). Breathing high levels in a closed room can cause fatigue, vomiting, dizziness, and possibly unconsciousness. Breathing, drinking, or touching large amounts of 1,1,2,2-tetrachloroethane for a long period of time can cause liver damage, stomachaches, or dizziness (ATSDR 2008). The oral slope factor and chronic RfD for 1,1,2,2-tetrachloroethane is $2x10^{-1}$ $(mg/kg\text{-}day)^{-1}$ and $2x10^{-3}$ (mg/kg-day), respectively.

Most 1,1,2,2-tetrachloroethane released to the environment eventually moves to the air or ground water. It does not attach to soil particles when released to land. When released to surface water, much of it will evaporate to the air while the rest may break down in the water. It takes about one year for half of the chemical to disappear from groundwater and two months in air.

Trichloroethene

Trichloroethene (also known as trichloroethylene) is a colorless, volatile liquid. It is nonflammable and has a sweet odor. The two major uses of trichloroethene are as a solvent to remove grease from metal parts and as a chemical that is used to make other chemicals. Trichloroethene has also been used as an extraction solvent for greases, oils, fats, waxes, and tars; by the textile processing industry to scour cotton, wool, and other fabrics; in dry cleaning operations; and as a component of adhesives, lubricants, paints, varnishes, paint strippers, pesticides, and cold metal cleaners (ATSDR 2019)

Based on sufficient evidence in humans regarding trichloroethene exposure and cancer, and evidence that high doses of trichloroethene can cause cancer in animals, trichloroethene is classified as a human carcinogen. There is strong evidence that trichloroethene can cause kidney cancer in people and some evidence that it causes liver cancer and malignant lymphoma (a blood cancer). Lifetime exposure to trichloroethene resulted in increased liver cancer in mice and increased kidney cancer in rats at relatively high exposure levels. There is some evidence for trichloroethene-induced testicular cancer and leukemia in rats and lymphomas and lung tumors in mice. There is also some evidence of an association between trichloroethene exposure and non-Hodgkin's lymphoma in humans (IRIS 2011; ATSDR 2019).

People who are overexposed to moderate amounts of trichloroethene may experience headaches, dizziness, and sleepiness; large amounts of trichloroethene may cause coma and even death. Some people who breathe high levels of trichloroethene may develop damage to some of the nerves in the face. Other effects seen in people exposed to high levels of trichloroethene include evidence of nervous system effects related to hearing, vision, and balance, changes in the rhythm of the heartbeat, liver damage, and evidence of kidney damage. Some people who get concentrated solutions of trichloroethene on their skin develop rashes. Relatively short-term exposure of animals to trichloroethene resulted in harmful effects on the nervous system, liver, respiratory system, kidneys, blood, immune system, heart, and body weight (ATSDR 2019). The oral slope factor and RfD for trichloroethene is $4.6x10^{-2}$ (mg/kg-day$^{)-1}$ and $5x10^{-4}$ (mg/kg-day), respectively (IRIS 2011).

Trichloroethene shows high mobility in soil. Trichloroethene partitions rapidly to the atmosphere from surface water. It has low volatility in soil. Trichloroethene has a low tendency to bioaccumulate in aquatic organisms and biomagnification does not seem to be important, although bioaccumulation in plants has been indicated (ATSDR 2019).

Vinyl chloride

Vinyl chloride is a manufactured substance that does not occur naturally; however, it can be formed in the environment when other manufactured substances, such as trichloroethene, trichloroethane, and tetrachloroethylene, are broken down by certain microorganisms. At room temperature and pressure, vinyl chloride is a colorless gas with a mild, sweet odor. Vinyl chloride is poorly soluble in water. Most of the vinyl chloride produced in the United States is used to make PVC, which consists of long repeating units of vinyl chloride. Vinyl chloride can migrate to groundwater and can be in groundwater due to the breakdown of other chemicals. Some vinyl chloride can dissolve in water (IRIS 2000). Overall, the data indicate that neither vinyl chloride nor its metabolites are likely to accumulate in plants, animals, or the human body (ATSDR 2006b; IRIS 2000).

Vinyl chloride is a known human carcinogen. The vinyl chloride RfD is $3x10^{-3}$ mg/kg-day and the RfC is $1x10^{-1}$ mg/m^3 (IRIS 2000). Because vinyl chloride usually exists in a gaseous state, you are most likely to be exposed to it by breathing it. If you breathe high levels of vinyl chloride, you will feel dizzy or sleepy. These effects occur within 5 minutes if you are exposed to about 10,000 ppm of vinyl chloride. People who breathe extremely high levels of vinyl chloride can die. Studies in animals show that extremely high levels of vinyl chloride can damage the liver, lungs, and kidneys. These levels also can damage the heart and prevent blood clotting. You can also be exposed to vinyl chloride by drinking water from contaminated wells. The effects of ingesting vinyl chloride are unknown. The liver is the most sensitive target organ for vinyl chloride toxicity for both intermediate- and chronic-duration inhalation and chronic-duration oral exposures (ATSDR 2006b).

Xylenes

Xylene, also known as xylol or dimethylbenzene, is primarily a synthetic chemical. It is a colorless, flammable liquid with a sweet odor. The term total xylenes refers to all three isomers of xylene (m-, o-, and p-xylene). Since xylene evaporates easily, most xylene that gets into soil and water (if not trapped underground) is expected to move into the air where it is broken down by sunlight into other less harmful chemicals within a couple of days. People are most likely to be exposed to xylene by breathing it in air contaminated with xylene vapors. Xylenes tend not to accumulate in the body, but may be sequestered briefly in fat tissues; elimination of xylene is slower in individuals with a greater percentage of body fat (ATSDR 2007b; IRIS 2003b).

There is insufficient information to determine whether or not xylene is carcinogenic (ATSDR 2007b; IRIS 2003b). The xylenes RfD is $2x10^{-1}$ mg/kg-day and the RfC is $1x10^{-1}$ mg/m^3 (IRIS 2003b). The primary effects of xylene exposure involve the nervous system by all routes of exposure, the respiratory tract by inhalation exposure, and, at higher oral exposure levels, liver, kidney, and body weight effects. Scientists have found that the three forms of xylene have very similar effects on health. Short-term exposure of people to high levels of xylene can cause irritation of the skin, eyes, nose, and throat; difficulty in breathing; impaired function of the lungs; delayed response to a visual stimulus; impaired memory; stomach discomfort; and possible changes in the liver and kidneys. Both short- and long-term exposure to high concentrations of xylene can also cause a number of effects on the nervous system, such as headaches, lack of muscle coordination, dizziness, confusion, and changes in one's sense of balance (ATSDR 2007b). The available studies indicate that xylenes are rapidly absorbed following both inhalation and oral exposure. Following absorption, considerable metabolism occurs, with the liver being the primary site of metabolism (IRIS 2003b).

5.2 Toxicological Profile for Methane

Methane is a colorless, odorless, flammable gas and the major component of natural gas (NRC 1984). In nature, methane is produced by the anaerobic bacterial decomposition of vegetable matter. Methane is an important source of hydrogen and some organic chemicals. Methane reacts with steam at high temperatures to yield carbon monoxide and hydrogen; the latter is used in the manufacture of ammonia for fertilizers and explosives. Other valuable chemicals derived from methane include methanol, chloroform, carbon tetrachloride, and nitromethane (Encyclopædia Britannica 2019).

Methane is lighter than air, having a specific gravity of 0.554. It is only slightly soluble in water. Methane in general is very stable, but mixtures of methane and air, with the methane content between 5 and 14 percent by volume, are explosive (Encyclopædia Britannica 2019). Methane is liquid under pressure (NJDOH 2016).

Little information is available on the toxicity of methane. It appears that toxic effects of methane, considered biologically inert, are related to the oxygen deprivation (asphyxiation) that occurs when methane is present in air at a high concentration (NRC 1984). Very high levels of methane can cause suffocation with symptoms of headache, dizziness, weakness, nausea, vomiting, loss of coordination and judgment, increased breathing rate, and loss of consciousness. Skin contact with liquefied methane can cause frostbite (NJDOH 2016).

6.0 Human Health Risk Assessment Findings

Risk characterization is the final step in an HHRA during which exposure estimates are combined with toxicity information to make qualitative and quantitative statements about risk and the conditions under which risk may occur. Risk characterization provides an overall depiction of the nature, magnitude, and likelihood of human health risks at a site and provides the basis for the selection of appropriate risk management options.

Exposure to vapors in landfill gas and groundwater were considered as a potentially complete route of exposure under the worst-case scenario assumption that a long-term failure in engineered protections (including the landfill cap and gas collection system) occurs at the OMF South, allowing for vapor intrusion from subsurface gas and underlying groundwater to indoor air.

Based on the comparison of available groundwater data to applicable risk-based screening levels, occupational exposure to COIs detected in underlying groundwater at the Midway Landfill via vapor intrusion is not expected to result in adverse chronic health effects.

In addition, occupational exposure to methane gas is not expected to result in adverse chronic health effects due to the relatively non-toxic nature of the gas. However, other occupational hazards associated with methane gas at the Midway Landfill may need to be considered and addressed through risk management efforts if Sound Transit selects the site for the future OMF South (see Section 7).

A high level of uncertainty remains regarding the potential risks associated with occupational exposures to VOCs and inorganic gases at the site due to a lack of sufficient and reliable data necessary to characterize human health risks. Although a number of toxic volatile compounds were identified in previous site investigations, these data were collected more than 25 years ago and likely do not represent current and future site conditions. An additional level of uncertainty exists regarding the potential for occupational exposure to COIs in landfill gas based on current and future site conditions and engineered controls. At this time, the migration of landfill gas through the subsurface to indoor and ambient air is controlled by the gas extraction system and the landfill cap. Based on the ROD, the City is required to ensure continued operation and maintenance of all components of the remedy (including the gas extraction system and the landfill cap) if any portion of the property is sold, leased, transferred, or otherwise conveyed. It is expected that future development of the OMF South at the Midway Landfill would include a gas extraction system and the landfill cap and other engineered protections to mitigate and monitor vapor intrusion of landfill gas (including methane) to indoor air.

However, in order to effectively quantify the risk associated with occupational exposures to COIs in landfill gas, additional sampling is needed to characterize site conditions and identify potential routes of exposure. Future sampling of landfill gas constituents should be conducted following an approach that generates the appropriate environmental data needed to characterize occupational exposures and evaluate potential health risks at the OMF South (e.g., post construction sub-slab soil gas and/or indoor air sampling). Pre-construction sampling of flare inlet gas and gas extraction wells could also be conducted to provide information on the COIs present in landfill gas at this time; however, concentrations of COIs in samples collected from the landfill gas collection system would not be appropriate for use in the assessment of occupational exposures at the OMF South as they are likely not representative of concentrations in the subsurface that may pose an unacceptable threat to indoor air quality in site buildings. At this point, quantification of any long-term worker risk is premature until representative data can be acquired.

7.0 Non-Toxicological Hazards Evaluation

Potential non-toxicological hazards at the OMF South are less a factor of exposure to the contaminants within the landfill and are more focused on site conditions at the landfill as a whole. As the landfill ages, material changes occur through the degradation of the solid waste material and the resulting production of liquid and gas. A more detailed background discussion of the landfill life cycle is available in the OMF South Landfill Evaluation Report (HDR 2019a). Some of the primary non-toxicological risk factors associated with redevelopment on a landfill include methane explosion risk, seismic events, and occupational exposure to site COIs during construction activities which are discussed below.

7.1 Methane Explosion

Decomposing solid waste generates landfill gas, of which methane is a primary constituent. The percentage of methane within landfill gas varies with time and other site-specific factors. Methane is an explosive hazard in the right concentration and under the right conditions. The Midway Landfill is currently generating landfill gas, which is collected by landfill gas wells, conveyed to a flare station by surface piping and vacuum blowers, and safely combusted. The landfill cap is a critical component of landfill gas control, eliminating the opportunity for gas to move through the landfill surface, and requiring landfill gas to progress through the landfill gas system. The development of the OMF South will require the reconstruction of portions, or all, of the landfill cap and gas collection system, depending on the construction design.

Further, the direct proximity of the OMF South to the landfill can create explosion risk if methane is able to intrude and build up in a confined space within the OMF South. In this case, if an ignition source was provided, an explosion could occur.

Explosion risk is present at the site and needs to be mitigated through engineering controls. Common means for protection would be the re-establishment of the landfill cap and gas collection system impacted during construction of the OMF South. This approach provides a methane barrier at the landfill surface and an active landfill gas collection system to create a positive draw on gas within the landfill.

Additional engineered protections can be incorporated into the OMF South design to mitigate the risk associated with a potential landfill cap leak and/or gas collection system failure for areas in contact with the landfill surface and subsequent migration of landfill gas into indoor air and confined spaces within the OMF South. An independent under slab methane barrier with passive gas ventilation could also be installed below building foundations and slabs to prevent vapor intrusion. This option would only be appropriate for three of the construction design approaches (Approaches 2, 3, and 4), which has portions of the OMF South constructed in contact with the landfill surface and a risk of gas intrusion through cracks in the slab and other vulnerabilities (see Section 2.4.3 for brief description of the each of the five construction design approaches). A methane barrier would not be required for yard slabs as these areas are able to vent to atmosphere. Approach 1 incorporates construction of the OMF South on an elevated platform making vapor intrusion of landfill gas unlikely since gas escaping from the landfill cap would dissipate prior to being able to enter the OMF South structure. Approach 5 incorporates construction of the OMF South on a slab foundation following the excavation of underlying solid waste. This approach would remove most of the landfill gas producing material during construction such that vapor intrusion would no longer be a concern. Approach 5 would not likely require an active landfill gas system, if one is required at all. However, if one were required, the system would be expected to be passive.

In addition to, or instead of, an independent methane barrier, gas sensors can be installed in occupied areas and in areas where site operations provide an ignition source. Sensors could be set to alarm at methane levels of 10% and 25% of the LEL. Appropriately classified electrical equipment can also help reduce potential ignition sources; however, considering the function of the OMF South, it is not reasonable to expect that all potential ignition sources can be eliminated.

Methane migration to in-ground, non-building, confined spaces, such as manholes and vaults, could occur through a leak in the landfill cap resulting in a methane explosion or asphyxiation hazard. These hazards can be managed through adherence to required confined space entry procedures including monitoring of methane and oxygen concentrations prior to entry.

If a seismic event were to occur, the site can be reviewed for visual indications of instability.

7.2 Seismic Considerations

Stability of a landfill mass can be different from developed sites on typical earth. A seismic and static stability analysis to demonstrate that a proposed landfill configuration will be stable is a requirement for new landfills. Old landfills may also have stability analysis requirements and are regularly inspected for signs of instability. Stability concerns have not been identified at Midway Landfill. The site configuration is primarily a backfill of a previous excavation and site slopes have no reported signs of instability.

All of the construction design approaches for the OMF South are expected to improve site stability. If Approach 1 is developed, the elevated platform will be designed to meet seismic standards. Approaches 2, 3, 4 and 5 will lower the landfill elevation and increase stability through the use of competent soil. Further geotechnical analysis can be performed to evaluate site seismic and static stability with the OMF South loading.

7.3 Hazards Associated with Construction Activities

The construction of the OMF South under all five construction design approaches require the disruption of established remedial systems, such as the continuity of the landfill cap and landfill gas collection system. These disruptions which, without adequate and proper controls, could temporarily expose construction workers to solid waste and landfill gas. Additionally, exposed areas may also generate dust and contaminated runoff that could impact the surrounding environment. Applicable regulatory requirements will need to be followed to provide continued protection of human health and the environment during construction of the OMF South.

An Environmental Protection Plan will likely be required to establish procedures to manage and monitor the waste excavation and handling process, including management of stormwater and landfill gas. In addition to continuous landfill gas management, measures will need to be established to prevent air intrusion into the landfill that could result in a landfill fire.

A project-specific Health and Safety Plan will also be required and will include stipulations that construction workers who may be exposed to potentially hazardous substances will be required to obtain the appropriate level of Hazardous Waste Operations and Emergency Response Standard (HAZWOPER) training.

8.0 Conclusions

The HHRA found that occupational exposures to VOCs in groundwater and to methane in landfill gas are not expected to result in adverse chronic health effects for any OMF South worker. However, the potential risk associated with occupational exposures to COIs in landfill gases could not be characterized due to a lack representative data. In order to quantify occupational risk at the OMF South, post-construction sampling of VOCs and toxic inorganic gases is needed (e.g., sub-slab soil gas and/or indoor air sampling) to provide an appropriate measure of the concentrations that workers may be exposed to at the OMF South.

In order to assess current COI concentrations in landfill gas, a pre-construction landfill gas investigation could be conducted. Potential landfill gas sampling options are discussed in Appendix B.

The non-toxicological hazards evaluated for the Midway Landfill can largely be managed through appropriate engineered protections, health and safety protocols, construction design standards, and site control and environmental protection plans. Risk management approaches for non-toxicological hazards will need to be developed based on the final selected OMF South construction approach.

Exposure Pathway Evaluation for
Midway Landfill

Figure 2: Indoor Air Screening Level Equations and Exposure Assumptions for Non-carcinogens

Comparison of Model Toxics Control Act (MTCA) Method C: Industrial Scenario and EPA Vapor Intrusion (VISL) Worker Scenario

	Method C: Indoor Air Cleanup Level – Noncarcinogens (Equation 750-1)	**USEPA VISL Worker Indoor Air Screening Level - Noncarcinogens**
Where:	$SL_{IA\,(nc)} = \frac{RfD \times ABW \times UCF \times HQ \times AT}{BR \times ABS \times ED \times EF \times ET}$	$SL_{IA\,(nc)} = \frac{UCF \times HQ \times AT}{ED \times EF \times ET \times \left(\frac{1}{RfC}\right)}$
Screening Level for Indoor Air (SL_{IA})	calculated (µg/m^3)	calculated (µg/m^3)
Noncancer (nc) Toxicity Values	contaminant specific Reference Dose (RfD) (mg/kg-day) as specified in WAC 173-340-708(7)	contaminant specific Reference Concentrations (RfC) (mg/m3)
Average Body Weight (ABW)	70 kg (adult)	NA
Unit Conversion Factor (UCF)	1,000 µg/mg	1,000 µg/mg
Breathing Rate (BR)	20 m^3/day (adult)	NA
Absorption Factor (ABS)	1 (unitless)	NA
Hazard Quotient (HQ)	1 (unitless)	1 (unitless)
Averaging Time (AT)	6 years	25 years
Exposure Duration (ED)	6 years	25 years
Exposure Frequency (EF)	365 days per year	250 days per year
Exposure Time	24 hours per day	8 hours per day

Figure 3: Indoor Air Screening Level Equations and Exposure Assumptions for Carcinogens

Comparison of Model Toxics Control Act (MTCA) Method C: Industrial Scenario and EPA Vapor Intrusion (VISL) Worker Scenario

	MTCA Method C: Indoor Air Cleanup Level – Carcinogens (Equation 750-2)	**USEPA VISL Worker Indoor Air Screening Level - Carcinogens**
Where:	$SL_{IA\,(c)} = \frac{Risk \times ABW \times UCF \times AT}{CPF \times BR \times ABS \times ED \times EF}$	$SL_{IA\,(c)} = \frac{Risk \times AT}{ED \times EF \times ET \times IUR}$
Screening Level for Indoor Air (SL_{IA})	calculated (µg/m^3)	calculated (µg/m^3)
Cancer (c) Toxicity Values	contaminant specific cancer potency factor (CPF) (kg-day/mg) as specified in WAC 173-340-708(8)	contaminant specific inhalation unit risk (IUR) (µg/$mg^3)^{-1}$
Average Body Weight (ABW)	70 kg (adult)	NA
Unit Conversion Factor (UCF)	1,000 µg/mg	NA
Breathing Rate (BR)	20 m^3/day (adult)	NA
Absorption Factor (ABS)	1 (unitless)	NA
Acceptable Cancer Risk	1 in 100,000 (unitless) or 10^{-5}	1 in 100,000 (unitless) or 10^{-5}
Averaging Time (AT)	75 years	70 years
Exposure Duration (ED)	30 years	25 years
Exposure Frequency (EF)	365 days per year	250 days per year
Exposure Time (ET)	24 hours per day	8 hours per day

Figure 4: Soil Vapor Intrusion Screening Level Equation (MTCA and USEPA VISL)

	Soil Gas Vapor Intrusion Screening Level Equation
Where:	$$SL_{SG} = \frac{SL_{IA}}{VAF}$$
Screening Level for Soil Gas based on Indoor Air Screening Level (SL_{SG})	calculated (µg/m^3)
Screening Level for Indoor Air (SL_{IA})	µg/m^3
Vapor Attenuation Factor (VAF)	0.03 for sub-slab/near source soil gas; 0.01 for deep soil gas[a] (unitless)

[a] Deep soil gas vapor screening levels are calculated for MTCA only.

Figure 5: Groundwater Vapor Intrusion Screening Level Equation (MTCA and USEPA VISL)

	Groundwater Vapor Intrusion Screening Level Equation
Where:	$$SL_{GW} = \frac{SL_{IA}}{VAF \times UCF \times H_{cc}}$$
Screening Level for Groundwater based on Indoor Air Screening Level (SL_{GW})	calculated (µg/L)

Appendix B: Landfill Gas Sampling Options

Landfill Gas Sampling Options

Introduction

This appendix discusses potential options for pre-construction sampling of landfill gas constituents (e.g., VOCs and inorganic gases) at the Midway Landfill. Landfill gas sample results can provide Sound Transit with a better understanding of the current conditions at the Midway Landfill and information about the types and concentrations of COIs found in the landfill gas. Sample results can inform decisions about the mitigation and/or management of risks associated with the potential exposure to VOCs and inorganic gases at the OMF South. However, pre-construction sample results would not be appropriate for use in quantitative exposure or risk assessment as they do not necessarily reflect the levels of contamination to which OMF South workers may be exposed in the future.

Potential Sampling Options

Potential landfill gas sampling options include: 1) flare inlet and extraction well gas sampling, 2) near surface gas sampling, and 3) shallow soil gas sampling. These sampling options and the applications and limitations of each in the context of the Midway Landfill are described below.

Collection of flare inlet and extraction well gas samples: Measurements of landfill gas constituents can be taken at depth using the existing landfill gas extraction system. Samples may be collected at the flare inlet and at individual wells located throughout the landfill. Samples collected from the flare inlet represent a composite of all gases and vapors contained within the landfill under the landfill cap. The flare inlet sample results could be compared to historic landfill gas data from the 1988 gas characterization study completed as part of the RI (Parametrix 1988a) and the 1992 source emission evaluation (Am Test-Air Quality Inc. 1992). This comparison may provide insight into changes in concentrations in landfill gas constituents over the last 30 years. Samples collected from individual extraction wells may also provide information about the distribution of VOC-containing waste and/or areas of higher or lower VOC concentrations at specific locations within the landfill.

These landfill gas data would not provide an actual measure of the concentrations of VOCs and inorganic gases that workers at the OMF South may come in contact with. These samples are collected deep beneath the landfill cap and landfill gas constituent concentrations are expected to change as the gases move horizontally and vertically in the subsurface prior to possible exposure through a leak in the landfill cap and into ambient air. Consequently, these data should not be used for quantitative exposure or risk assessment.

Monitoring of near surface gas: Near surface gas monitoring measures the concentrations of gases at a point no higher than 4 inches above the surface of the landfill. This type of sampling can qualitatively indicate whether high levels of landfill gas are escaping from the landfill surface or if the landfill cap and gas extraction system are working effectively. Near surface gas monitoring often uses a portable instrument to screen for high levels of landfill gas along with collection of grab samples for laboratory analysis. Results from near surface gas sampling can be greatly influenced by meteorological conditions. Moderate winds can quickly dilute near surface gas concentrations.

Near surface gas data can help identify point sources of high concentrations of landfill gases (caused by leaks in the landfill cap). However, because of expected changes to the site due to the construction of the OMF South (e.g., the possible removal of underlying waste material and changes in the configuration of the landfill cap, etc.), pre-construction near surface gas samples are not expected to provide an actual measure of the concentrations of VOCs and inorganic gases that workers at the OMF South may come in contact with in the future. Changes in site conditions are likely to result in a difference in pre- and post-construction near surface gas results.

Near surface gas sampling can be conducted following a planned or unplanned breach in the landfill cap. In this case, once the landfill cap is penetrated, near surface gas sampling can be used to measure landfill gas constituent concentrations in gas escaping from the landfill. These data provide information about potential exposures to VOCs and inorganic gases at the specific location and time of the breach. Because VOC and inorganic gas concentrations can vary spatially throughout a landfill, near surface gas results from a breach in one location within the landfill may not be representative of near surface gas results at other locations where a breach may occur.

Exposure to VOCs and inorganic gases caused by a breach in the landfill cap would be influenced by the size and location of the breach, the location of waste within the landfill relative to the breach, the construction and configuration of the OMF South, and other site-specific factors. Pre-construction sampling of a breach in the landfill cap would not be expected to reflect the levels of contamination to which OMF South workers may be exposed in the future.

A planned breach or penetration of the landfill cap would likely require regulatory coordination and approval, and the logistics and costs of sampling a planned breach are likely to be prohibitive; as a result, near surface gas sampling of a planned breach are not recommended.

Collection of shallow soil gas samples: Shallow soil gas samples can be used to provide a measure of VOC and inorganic gas concentrations in soil gas near buildings or developable areas. Sample results can then be used to determine if constituent concentrations in the subsurface are high enough to pose a potentially unacceptable threat to indoor air quality in current or future site buildings.

Shallow soil gas sampling involves the installation of a temporary or permanent soil gas sampling probe to a recommended depth of no less than 5 feet bgs followed by the collection of a sample into an evacuated sampling canister. Due to the possibility of diluting the collected soil gas with atmospheric air and to minimize barometric pumping effects, samples should seldom be collected from depths shallower than 5 feet bgs (Ecology 2018a).

The Midway Landfill is currently covered by a multi-layered landfill cap comprised of a top layer of 12-inch-thick topsoil planted with shallow rooted grasses followed by a 12-inch-thick drainage layer, a layer of filter fabric, drainage net, and 50-mil HDPE flexible membrane. Below the HDPE membrane is a 12-inch-thick layer of low permeability soil/clay material (USEPA 2000a, 2015a). The depth of the prescribed cover over the geosynthetic membrane in the landfill cap is variable throughout the landfill due to grading activities conducted to maintain effective surface water management over the life of the landfill. Cover soil is estimated to be as deep as 14 feet in places.

If this sampling option was selected for the Midway Landfill prior to construction of the OMF South, shallow soil gas samples would need to be collected at locations where the cover soil is greater than 5 feet in order to avoid disturbing the integrity of geosynthetic membrane in the landfill cap. Shallow soil gas results should be reviewed with the understanding that sample results are likely to vary based on sample location relative to VOC and inorganic gases concentrations in the landfill, whether there is a leak in the landfill cap in the vicinity of the sample location, and other site-specific factors.

As discussed earlier in the context of near surface gas sampling, shallow soil gas samples could be collected following a breach in the cap; however, pre-construction shallow soil gas results are not expected to be representative of levels of contamination to which OMF South workers may be exposed in the future.

Potential Sampling Approach

In order to provide Sound Transit with information about the types and concentrations of VOCs and inorganic gases found in landfill gas at the Midway Landfill under current site conditions, the following sampling approach could be implemented prior to construction of the OMF South.

- Phase 1: Landfill Gas Characterization

  Conduct limited landfill gas sampling of the flare inlet for comparison to historical data from the 1988 gas characterization study (Parametrix 1988a) and the 1992 source emission evaluation (Am Test-Air Quality Inc. 1992). Samples collected from the flare inlet would be analyzed for those VOCs and inorganic gases detected in the 1988 and

1992 samples. Flare inlet sample results would provide information on VOCs and inorganic gases currently present in extracted landfill gas.

- Phase 2: Landfill Gas Constituent Distribution

  Depending on the results of flare inlet gas sampling, Sound Transit may opt to conduct landfill gas sampling of individual extraction wells throughout the landfill footprint. Samples collected from the individual wells would be analyzed for those VOCs and inorganic gases detected in flare inlet gas samples. Individual extraction well sample results would provide information on the distribution of VOCs and inorganic gases by well location throughout the landfill and within the proposed OMF South footprint.

Near surface sampling and shallow soil gas sampling are not recommended at this time but may be considered in the future depending on the selected construction approach, potential changes in site conditions, and the results of the landfill gas characterization and constituent distribution sampling described above.

Executive Summary

A Human Health Risk Assessment (HHRA) was prepared for the Midway Landfill as a potential site alternative for Sound Transit's Operations and Maintenance Facility South (OMF South) in January 2020 (HDR 2020). Sound Transit is currently implementing a system-wide expansion of the Link light rail system and is evaluating the Midway Landfill (Comprehensive Environmental Response, Compensation, and Liability Information System [CERCLIS] Identification Number: WAD 980638910) as a potential site alternative in the OMF South Draft Environmental Impact Statement (EIS) (HDR 2019a).

The HHRA evaluated several contaminants of interest (COIs) identified during previous site investigations of the Midway Landfill including a number of volatile organic compounds (VOCs), hydrogen sulfide, and methane (HDR 2020).

Several potentially complete occupational routes of exposure to COIs in landfill waste, gas, and groundwater at the OMF South were also identified in the HHRA (HDR 2020). These potentially complete exposure routes include:

- Inhalation of Indoor Air for Onsite Office and Maintenance Shop Workers,
- Inhalation of Air in Subsurface Confined Spaces (e.g., utility trenches and vaults) for Construction Workers,
- Inhalation of Outdoor Air for Maintenance Shop, Yard, and Construction Workers, and
- Direct Contact with Waste and Contaminated Soil for Construction Workers (HDR 2020).

The HHRA found that occupational exposures to VOCs in groundwater and to methane in landfill gas (LFG) are not expected to result in adverse chronic health effects for potential future OMF South workers (HDR 2020). However, the potential risk associated with occupational exposures to VOCs and inorganic gases detected in LFGs could not be characterized due to a lack representative data (HDR 2020).

In order to provide Sound Transit with information about the types and concentrations of VOCs and inorganic gases found in LFG at the Midway Landfill under current site conditions, Parametrix, Inc. (Parametrix) conducted a pre-construction LFG sampling event at the Midway Landfill on April 9, 2020. While these data are not intended (or appropriate) for use in quantitative risk assessment at OMF South, they can inform decisions about the mitigation and/or management of risks associated with the potential exposure to VOCs and inorganic gases during the construction and operation of OMF South.

LFG samples were collected directly from the active gas extraction system. LFG is extracted through the onsite extraction wells at the landfill and routed to a permanent blower/flare system where the extracted gas is supplemented with natural gas and then burned before discharge to the atmosphere (USEPA 2000, 2015).

LFG samples were collected from a manifold inlet to the flare and several gas extraction wells located within the proposed OMF South facility footprint that were still producing a measureable amount of LFG (according to information provided by SPU). Sampled wells were selected based on their proximity to proposed geotechnical borings. In addition, air grab sampling was conducted in areas where the landfill cap had been breached prior to repair during a geotechnical investigation completed in March-April 2020.

This addendum supplements the Midway Landfill HHRA (HDR 2020) with a summary of the April 2020 sampling activities and results, and compares results to historic (1988 and 1992) LFG concentrations previously presented in the HHRA. A qualitative evaluation of the April 2020 results and subsequent updates to the information presented in the HHRA are also included.

LFG Sampling

On April 9, 2020, Parametrix collected 11 samples from a manifold inlet and nine landfill extraction system wells. Three near-surface gas samples were collected in the vicinity of three geotechnical borings where the landfill cover system had been breached (see Figure 1 for approximate sample locations). The LFG extraction system was operating during the sample event and as a result, gas contained in the landfill was under vacuum conditions at the time of sample collection.

All samples were analyzed by Environmental Analytical Services, Inc. (EAS) for:

- VOCs by U.S. Environmental Protection Agency (USEPA) Method TO-15 (USEPA 1999),
- Hydrogen sulfide by USEPA Method M16 (USEPA 2017a), and
- Carbon dioxide and methane by ASTM D1945 (ASTM 2019).

LFG Sample Results

Benzene, ethylbenzene, and hydrogen sulfide were found in the manifold inlet and several extraction wells at concentrations that exceed one or more regulatory screening levels. Methane was detected in the manifold inlet and all of the extraction well samples (with the exception of GW-7) at concentrations that exceed the lower explosive limit (LEL) of 5% (WAC 173-304-460).

Three VOCs (ethylbenzene, toluene, and total xylenes) were detected in one air grab sample. Methane was not detected in any air grab samples.

Comparison to Historic LFG Data

Manifold inlet and extraction well sample results from the April 2020 sampling event were compared to the 1988 gas characterization study which was completed as part of the Remedial Investigation (RI) (Parametrix 1988) and the 1992 source emission evaluation (Am Test-Air Quality Inc. 1992) in order to provide insight into changes in concentrations in LFG constituents over the last 25 to 30 years. The RI was conducted by the City of Seattle (City) and the Washington State Department of Ecology (Ecology) in 1988 to investigate the impact of the landfill on the environment.

Average VOC concentrations in subsurface and flare inlet (or manifold inlet) gas combined have decreased since 1988 and 1992 for all detected VOCs. Compared to 1988 LFG results, the average concentrations of vinyl chloride, toluene, total xylenes, benzene, and ethylbenzene in subsurface gas (LFG extraction wells and manifold or flare inlet combined) have decreased by 98%, 91%, 85%, 52% and 35%, respectively. Hydrogen sulfide concentrations have decreased by 66% since 1988. When compared to the 1992 flare inlet results, vinyl chloride, toluene, total xylenes, benzene, and ethylbenzene concentrations have decreased by 95%, 90%, 95%, 70% and 82%, respectively.

Methane concentration data collected from the LFG extraction system by Seattle Public Utilities (SPU) on a monthly basis from January 2015 to August 2019 were compared to April 2020 methane results for sampled extraction wells. Methane was detected in all extraction wells and the manifold inlet sample at concentrations within (near the lower end of) the range of the 2015-2019 data.

LFG Sampling Findings

The April 2020 LFG extraction system sample results indicate that several VOCs remain in LFG at the site; however, the VOCs with the highest concentrations in 2020 (benzene, ethylbenzene, and hydrogen sulfide) have decreased substantially since 1988.

VOC results from the manifold inlet and extraction wells and from co-located wells demonstrate that concentrations can vary significantly by depth and by location throughout the landfill footprint.

The sampled extraction wells with the highest concentrations of benzene, ethylbenzene, and hydrogen sulfide include GW-42S and GW-42D and GW-48S and GW-48D.

HHRA Updates and Conclusions

The April 2020 LFG sampling event did not provide any new information that would result in a change in the current conceptual site model (CSM) included in Appendix A of this addendum and described in detail in the HHRA (HDR 2020). The primary source of Contaminants of Potential Concern (COPCs) at the site, chemical release mechanisms and environmental transport processes, and potentially complete routes of exposure for specific occupations at the OMF South depicted in the CSM remain the same as those presented in the HHRA (HDR 2020). Overall, the HHRA findings and conclusions have not changed.

1.0 Introduction

A HHRA was prepared for the Midway Landfill as a potential site alternative for Sound Transit's OMF South in January 2020 (HDR 2020). Sound Transit is currently implementing a system-wide expansion of the Link light rail system and is evaluating the Midway Landfill (CERCLIS Identification Number: WAD 980638910) as a potential site alternative in the OMF South Draft Environmental Impact Statement (EIS) (HDR 2019a).

The purpose of the HHRA was to assess potential chronic health risks to Sound Transit personnel who work at the future site should it be selected for the OMF South and waste be maintained on site. Non-Toxicological hazards including acute, physical risks associated with constructing and operating the OMF South over a waste mass were also discussed.

The HHRA evaluated several COIs detected in groundwater and LFG during previous site investigations of the Midway Landfill. The COIs found in onsite groundwater wells include dissolved iron, manganese, chloride, sulfate, 1,4-dioxane, 1,1-dichloroethane, cis-1,2-dichloroethene, and vinyl chloride. The COIs found in onsite LFGs include methane, hydrogen sulfide, and numerous volatile organic compounds (VOCs) (including ethylbenzene, vinyl chloride, total xylenes, toluene, and benzene which were found most frequently and in the highest concentrations). The HHRA provides a summary of findings and additional details about the previous site investigations (HDR 2020).

Several potentially complete occupational routes of exposure to COIs in landfill waste, gas, and groundwater at the OMF South were also identified in the HHRA (HDR 2020). These potentially complete exposure routes include:

- Inhalation of Indoor Air for Onsite Office and Maintenance Shop Workers,
- Inhalation of Air in Subsurface Confined Spaces (e.g., utility trenches and vaults) for Construction Workers,
- Inhalation of Outdoor Air for Maintenance Shop, Yard, and Construction Workers, and
- Direct Contact with Waste and Contaminated Soil for Construction Workers

These potential routes of exposure are based on the assumptions that construction of the OMF South may result in future site conditions that could allow for vapor intrusion from subsurface gas and underlying groundwater to indoor air (HDR 2020).

The HHRA found that occupational exposures to VOCs in groundwater and to methane in LFG are not expected to result in adverse chronic health effects for potential future OMF South workers (HDR 2020). However, the potential risk associated with occupational exposures to VOCs and inorganic gases detected in LFGs could not be characterized due to a lack representative data (HDR 2020). Although a number of toxic VOCs were identified in previous site investigations, these data were collected more than 25 years prior to completion of the HHRA and likely do not represent current or future site conditions.

The HHRA determined that in order to quantify potential future occupational risk to LFGs, *post-construction* sampling of VOCs and toxic inorganic gases is needed to provide a representative measure of the concentrations that workers may be exposed to at OMF South. Any future post-construction sampling of LFG constituents should be conducted following an approach that generates the representative environmental data needed to characterize occupational exposures and to evaluate potential health risks at the OMF South (such as sub-slab soil gas and/or indoor air sampling). Post-construction sub-slab soil gas and/or indoor air sampling results could then be compared to the appropriate risk-based screening levels (e.g., USEPA Worker Air Vapor Intrusion Screening Levels [VISLs] for Sub-slab or Near Source Soil Gas [USEPA 2019], USEPA Worker VISLs for Indoor Air [USEPA 2019], Model Toxics Control Act [MTCA] Method C Sub-slab Soil Gas Screening Levels [WAC 173-340-745], and MTCA Method C Indoor Air Screening Levels [WAC 173-340-750]).

However, in order to provide Sound Transit with information about the types and concentrations of VOCs and inorganic gases found in LFG at the Midway Landfill under current site conditions, Parametrix conducted a pre-construction LFG sampling event at the Midway Landfill on April 9, 2020.

LFG samples were collected directly from the active LFG extraction system which has been in operation since 1985. The extraction system places the landfill under vacuum conditions to pull gases from the underlying waste material. LFG is extracted through the onsite extraction wells at the landfill and routed to a permanent blower/flare system where the extracted gas is supplemented with natural gas and then burned before discharge to the atmosphere (USEPA 2000, 2015).

LFG samples were collected from a manifold inlet to the flare and several gas extraction wells located within the proposed OMF South facility footprint that were still producing a measureable amount of LFG (according to information provided by SPU). Sampled wells were selected based on their proximity to proposed geotechnical borings. In addition, three air grab samples were collected in areas where the landfill cap had been breached prior to repair during a geotechnical investigation conducted in March-April 2020.

This addendum supplements the Midway Landfill HHRA (HDR 2020) with a summary of the April 2020 sampling activities and results, and compares these results to historic LFG concentrations presented in the HHRA. An evaluation of the April 2020 results and subsequent updates to the information presented in the HHRA are also included.

2.0 LFG Sampling

The Midway Landfill is covered with a multilayered engineered cap (landfill cap) and a gas extraction system is in place and operating throughout the landfill to control subsurface migration of LFG to indoor and ambient air. Ecology oversees the City's operation and maintenance for the landfill cover system, gas extraction system, and surface water control systems constructed under the Consent Decree (Ecology 1990).

LFG is extracted through the onsite extraction wells at the landfill and routed to a permanent blower/flare system where the extracted gas is supplemented with natural gas and then burned before discharge to the atmosphere (USEPA 2000, 2015). Additional natural gas is needed for combustion due to the low volume of LFG currently generated at the site.

The landfill cap is comprised of a top layer of 12-inch-thick topsoil planted with shallow rooted grasses followed by a 12-inch-thick drainage layer, a layer of filter fabric, drainage net, and 50-mil High-Density Polyethylene (HDPE) flexible membrane. Below the HDPE membrane is a 12-inch-thick layer of low permeability soil/clay material (USEPA 2000, 2015). The depth of the prescribed cover over the geosynthetic membrane in the landfill cap is variable throughout the landfill due to grading activities conducted to maintain effective surface water management over the life of the landfill. Cover soil is estimated to be as deep as 14 feet in places.

The cap provides a barrier which, along with the operating gas extraction system (constructed in 1985), reduces the migration of volatile compounds found in LFG and groundwater to the surface where they may enter future onsite buildings and/or outdoor air. Migration of volatile compounds through the landfill cover is only possible if the gas extraction and cover system were compromised.

The HHRA considers exposure to vapors from LFG and groundwater a potentially complete route of exposure under the worst-case scenario assumption that a long-term failure in engineered protections (including the landfill cap and gas collection system) occurs at the OMF South, allowing for vapor intrusion from subsurface gas and underlying groundwater to indoor air (HDR 2020).

In order to characterize the types and concentrations of COIs currently found in the LFG, samples were collected directly from the LFG extraction system and analyzed for those COIs that were previously detected in historic LFG samples. In addition, air grab samples were collected in the vicinity of three geotechnical borings where the landfill cover system had been breached. The sampling approach, sample locations, and depths of the sampled wells are described in Section 2.2. Appendix B contains well logs for the sampled wells and Figure 1 shows the sampled wells and boring locations.

2.1 Sampling Approach

Prior to sampling, Parametrix selected several extraction wells within the proposed OMF South facility footprint that were producing measurable amounts of methane gas (according to information provided by SPU). These extraction wells were also selected based on their proximity to the proposed geotechnical borings where air samples were collected. Co-located shallow and deep wells were selected where possible. A manifold inlet to the flare station (located to the north/northwest of the sampled wells) was also identified for sampling.

The sampled LFG extraction wells are listed below along with nearby proposed (or completed) borings (Figure 1 shows the sampling locations).

- GW-52S [S=shallow] and GW-52D [D=deep] located near B-1.
- GW-7 located near B-2.
- GW-38S and GW-38D located near B-3.
- GW-48S and GW-48D located near B-4.
- GW-42S and GW-42D located near B-5.

Only borings B-2, B-4, and B-5 were completed at the time of the gas sampling.

Collection of Manifold and Extraction Well Gas Samples:

Samples were collected from a manifold inlet and individual extraction wells located throughout the landfill. Samples were collected directly from manifold inlet and extraction well sample ports. Samples collected from the manifold inlet represent a composite of all gases and vapors contained within the landfill under the landfill cap. Measurements of LFG constituents were taken at depth using existing gas extraction wells. Samples collected from individual extraction wells provide information about the distribution of VOC-containing waste and/or areas of higher or lower VOC concentrations at specific locations within the landfill.

Collection of Air Grab Samples:

In addition to samples collected directly from the LFG extraction system, air grab samples were collected in areas where the landfill cap had been breached during a geotechnical investigation conducted in March-April 2020. Samples were collected a couple inches above the ground at the breach in the liner.

2.2 April 2020 Sampling Event

On April 9, 2020, Parametrix collected 11 samples from a manifold inlet (MAN-1 and MAN-2 [duplicate]) and nine landfill extraction system wells (GW-7, GW-38S and GW-38D, GW-42S and GW-42D, GW-48S and GW-48D, and GW-52S and GW-52D). Three near-surface gas samples were collected in the vicinity of three geotechnical borings (B-2, B-4, and B-5) where the landfill cover system had been breached. The LFG extraction system was operating during the sample event and as a result, gas contained in the landfill was under vacuum conditions at the time of sampling. Figure 1 shows approximate sample locations.

The following samples were collected from the manifold inlet on April 9, 2020.

- MAN-1
- MAN-2 (duplicate sample of MAN 1)

LFG system extraction wells have been installed at specific locations and depths throughout the landfill to apply different vacuum pressure at different depths in underlying waste material. Shallow and deep wells are co-located in several locations throughout the landfill footprint. The depth of each sampled gas extraction well is provided below. Well logs are included in Appendix B. The following samples were collected on April 9, 2020.

- GW-7 – This sample was collected from extraction well GW-7 which has a depth of 70 feet below ground surface (bgs).
- GW-38S and GW-38D – These samples were collected from two co-located extraction wells (GW-38S and GW-38D). GW-38S has a depth of 56 feet bgs and GW-38D has a depth of 112 feet bgs.
- GW-42S and GW-42D – These samples were collected from two co-located extraction wells (GW-42S and GW-42D). GW-42S has a depth of 32 feet bgs and GW-42D has a depth of 64 feet bgs.
- GW-48S and GW-48D – these samples were collected from two co-located extraction wells (GW-48S and GW-48D). GW-48S has a depth of 49 feet bgs and GW-48D has a depth of 112 feet bgs.
- GW-52S and GW-52D – These samples were collected from two co-located extraction wells (GW-52S and GW-52D). GW-52S has a depth of 30 feet bgs and GW-52D has a depth of 64 feet bgs.

Three geotechnical borings were completed through the exposed and breached landfill cap between March 24 and April 1, 2020. Two borings could not be completed at the time of sampling due to restrictions associated with the Covid-19 pandemic. The completed borings ranged in depth from 120 feet bgs to 150 feet bgs. Air grab samples B-2, B-4, and B-5 were collected in the vicinity of these borings on April 9, 2020. At the time of sampling, the temperature was 42 degrees Celsius. The weather was noted as mostly sunny with calm winds and a steady barometric pressure of 30.30 inches mercury throughout the sampling.

Figure 1 shows the sampled wells and boring locations.

The field crew sampled the manifold inlet and extraction wells using Entech Bottle Vacs with a Quick Connect Adapter. The field crew collected the samples by connecting the Quick Connect

Adapter to the sample port and then connecting the Entech Bottle Vac to the adapter/sample port assembly. The field crew listened for air rushing into the canister and kept the Bottle Vac on the assembly for at least 1 minute or until the Bottle Vac reached a maximum pressure of 5 pound-force per square inch. The field crew then removed the Quick Connect Adapter to stop sampling. Air grab samples were collected by attaching sample tubing to an Entech Bottle Vac and opening the bottle for at least 1 minute or until the Bottle Vac reached a maximum pressure of 5 pound-force per square inch. After collection, all samples were shipped to EAS for analysis.

EAS analyzed samples for the following COIs previously detected in historic LFG samples:

- VOCs including benzene, chlorobenzene, chloromethane, 1,1-dichloroethane, 1,2-dichloroethane, 1,1-dichloroethene, trans-1,2-dichloroethene, ethylbenzene, dichloromethane (or methylene chloride), 4-methyl-2-pentanone (or methyl isobutyl ketone), styrene, 1,1,2,2-tetrachloroethane, tetrachloroethene, toluene, 1,1,1-trichloroethane, trichloroethene, vinyl acetate, vinyl chloride, total xylenes, tetrahydrofuran, trichlorofluoromethane, chloroethane (ethyl chloride), 1,1,2-trichloro-1,2,2-trifluoromethane (Freon 113), cis-1,2-dichloroethene, 1,4-dichlorobenzene, and 1,2-dichlorobenzene by USEPA Method TO-15 (USEPA 1999),
- Hydrogen sulfide by USEPA Method M16 (USEPA 2017a), and
- Carbon dioxide and methane by ASTM D1945 (ASTM 2019).

2.3 Data Validation

A Stage 2A data validation and data quality assessment was performed by Alta on the sample results for the additional site characterization efforts conducted by Parametrix on April 9, 2020, at the Midway Landfill (see Appendix C for the full quality assurance/quality control [QA/QC] review memorandum). Sampling procedures and the QA/QC review followed guidelines set forth in the following documents:

- ≠ Sampling Instructions for Collecting Samples in Entech Bottle Vacs (EAS no date) – This sampling procedure is provided in Appendix C. Parametrix followed this sampling procedure in lieu of a Quality Assurance Project Plan.
- ≠ National Functional Guidelines for Organic Superfund Methods Data Review (USEPA 2017b)
- ≠ Guidance for Labeling Externally Validated Laboratory Analytical Data for Superfund Use (USEPA 2009)
- ≠ USEPA Guidance on Environmental Data Verification and Data Validation (USEPA 2002)

2.3.1 Data Accuracy and Precision

Based on the data quality review, Alta determined the laboratory and field data to be of acceptable quality, with the exception of MAN-1, B-2, and GW-52D, which were rejected (R) based on insufficient sample volume.

2.3.1.1 Accuracy

Alta's Quality Assurance Officer (QAO) did not qualify any data based on accuracy results (surrogate recoveries and laboratory control samples).

2.3.1.2 Precision

Alta's QAO did not qualify any data based on precision results (laboratory control sample duplicates).

2.3.2 Data Sensitivity

All laboratory reporting limits were below screening levels.

2.3.3 Data Usability

Three samples were rejected (MAN-1, B-2, and GW-52D); therefore, the calculated completeness for this sampling event is 79%.

2.4 Data Limitations

It is important to note the limitations of the April 2020 LFG data; particularly in the application and interpretation of these data in the context of occupational exposure and risk assessment. These limitations are discussed below.

2.4.1 Subsurface LFG Data Limitations

As discussed in the HHRA (HDR 2020), samples collected directly from the LFG extraction system are not representative of VOC concentrations in subsurface gas that could pose an unacceptable risk to indoor air quality, and should not be used to quantify occupational exposures and resulting risk for the following reasons: 1) these samples were collected under vacuum conditions from varying depths within the landfill and therefore are not likely to be representative of gases that may be escaping the landfill cap, and 2) these samples are not likely to be representative of gases that would be found near the surface (where exposure occurs) due to differences in attenuation prior to sample collection.

In addition, subsurface LFG samples were collected from a relatively small number of sample locations within a large area (>60 acres), and during a single (one-day) sampling event and short sampling duration (one minute). Consequently, these results are representative of LFG concentrations at one point in time under specific conditions. These data do not capture potential fluctuations in concentrations due to seasonal variation and changes in weather, or due to changes in site conditions that might be caused by waste removal and/or OMF South construction activities. In addition, the underlying waste type and conditions and applied vacuum pressure and resulting radius of influence for each individual LFG extraction wells is not known. These factors may affect VOC and inorganic gas concentrations in the sampled wells.

Despite the limitations of these data for use in exposure assessment and quantitative risk assessment, these data are helpful in understanding current concentrations and types of VOCs and inorganic gases found in LFG at the site, and can inform decisions about the mitigation and/or management of risks associated with the potential occupational exposures during and following construction of OMF South.

2.4.2 Air Grab Sample Limitations

The interpretation and application of air grab sample results in understanding potential occupational exposures at OMF South is extremely limited due to the small sample volume (less than one liter) and short sampling duration (one minute). These factors may result in very low VOC concentrations in air (below detection limits) and do not capture fluctuations in concentrations due to changes in temperature and barometric pressure over a more representative exposure period (8 hours or more).

2.5 Comparison Screening Levels

In order to provide some context to the VOC concentrations in LFG extraction wells and the manifold inlet, the following regulatory screening levels for deep soil and near source soil gas for occupational exposures are included in Table 1 of this report:

- MTCA Method C Deep Soil Gas Screening Levels (for samples collected deeper than 15 feet bgs) (WAC 173-340-745), and
- USEPA Worker Air VISL for Sub-slab or Near Source Soil Gas (USEPA 2019).

These regulatory screening levels are provided for contextual purposes only and, as previously discussed in the HHRA (HDR 2020), are not used to identify COPCs in LFG extraction system samples.

No risk-based screening levels for methane are available for comparison due to a lack of toxicological effects. However, methane is highly flammable, can explode at concentrations between 5% (LEL) and 15% (upper explosive limit), and is a simple asphyxiant that can cause death at concentrations much higher than the explosive range (5-15%). Methane concentrations are compared to the LEL in the HHRA and in this addendum (WAC 173-304-460).

2.6 LFG Sample Results

LFG sample results from the onsite extraction wells and the manifold inlet are presented in Table 1 (VOCs) and Table 2 (methane) and are discussed in detail below.

2.6.1 Manifold Inlet Sample Results

An original/duplicate sample pair (MAN-1 and MAN-2) was collected from the manifold inlet (shown in Figure 1) and represents a composite of all gases and vapors contained within the landfill under the landfill cap. The original sample (MAN-1) did not have sufficient sample volume and was rejected; therefore, results for this sample are not discussed.

The following VOCs were found in the duplicate manifold inlet sample (MAN-2): benzene, chlorobenzene, 1,1-dichloroethane, ethylbenzene, tetrachloroethene, toluene, vinyl chloride, total xylenes, tetrahydrofuran, trichlorofluoromethane, chloroethane, cis-1,2-dichloroethene, and hydrogen sulfide. Of these detected VOCs, benzene and ethylbenzene exceeded one or more regulatory screening level (Table 1).

- MAN-2
    - Benzene = 492 µg/m^3 (compared to USEPA VISL = 524 µg/m^3 and MTCA Method C Deep Soil SL = 320 µg/m^3)
    - Ethylbenzene = 13,362 µg/m^3 (compared to USEPA VISL = 1,640 µg/m^3 and MTCA Method C Deep Soil SL = 100,000 µg/m^3)

Methane was detected in the manifold inlet sample at 13.48%, which exceeds the LEL of 5% (Table 2).

2.6.2 Extraction Well Sample Results

Nine samples were collected from LFG extraction wells; however, one sample (GW-52D) was rejected due to insufficient sample volume; therefore, results for this sample are not discussed.

The following VOCs were found in the extraction wells: benzene, chlorobenzene, 1,1-dichloroethane, ethylbenzene, dichloromethane, tetrachloroethene, toluene, trichloroethene, vinyl chloride, total xylenes, tetrahydrofuran, trichlorofluoromethane, chloroethane, cis-1,2-dichloroethene, and hydrogen sulfide. Table 1 summarizes the extraction well results. Of these detected VOCs, benzene, ethylbenzene, and hydrogen sulfide exceed one or more regulatory screening level. These results are shown in Table 1.

Of the sampled wells, benzene was detected at the highest concentration in GW-48D (1,701 µg/m^3 relative to the USEPA VISL of 524 µg/m^3 and the MTCA Method C Deep Soil SL of 320 µg/m^3). Benzene in this extraction well is approximately three times higher than in the manifold inlet and the co-located shallower well (GW-48S) (492 µg/m^3 and 549 µg/m^3, respectively). The next highest benzene concentrations were found in GW-42S and GW-42D, which are 550 µg/m^3 and 535 µg/m^3, respectively. All other extraction wells had benzene concentrations less than the average represented by the manifold inlet sample results (MAN-2).

Ethylbenzene and hydrogen sulfide were detected at the highest concentrations in GW-42S (25,679 µg/m^3 [relative to the USEPA VISL of 1,640 µg/m^3 and the MTCA Method C Deep Soil SL of 100,000 µg/m^3] and 32,297 µg/m^3 [relative to the USEPA VISL of 292 µg/m^3], respectively). This extraction well is one of the shallower sampled wells (completed to a depth of 32 feet bgs). Ethylbenzene in this extraction well is approximately two times higher than in the manifold inlet and the co-located deeper well (GW-42D) (13,362 µg/m^3 and 9,927 µg/m^3, respectively). The next highest ethylbenzene concentration detected in the extraction wells was in GW-48D at 13,207 µg/m^3; the ethylbenzene concentration for the co-located shallow well GW-48S is 1,231 µg/m^3. All other extraction wells had ethylbenzene concentrations less than the average represented by the manifold inlet sample (MAN-2).

Hydrogen sulfide in GW-42S is approximately 1.5 times higher than in the co-located deeper well (GW-42D) (18,072 µg/m^3 relative to the USEPA VISL of 292 µg/m^3) and orders of magnitude higher than in the manifold inlet sample (124 µg/m^3). The next highest hydrogen sulfide concentrations were found in GW-48S and its co-located deeper well (GW-48D) (16,288 µg/m^3 and 12,500 µg/m^3, respectively). All other extraction wells (with the exception of GW-7 which was below the detection limit) had hydrogen sulfide concentrations greater than the average represented by the manifold inlet sample results (MAN-2).

Methane was detected in all of the extraction well samples (Table 2). Results ranged from 0.72% (GW-7) and 20.42% (GW-38D). Methane exceeds the LEL in all wells with the exception of GW-7.

2.6.3 Air Grab Samples Results

Three air grab samples were collected in the vicinity of the geotechnical borings where the cap had been breached. However, one sample (B-2) was rejected due to insufficient sample volume; therefore, results for this sample are not discussed.

Three VOCs (ethylbenzene, toluene, and total xylenes) were detected in the air grab samples. The majority of analyzed VOCs were not detected in the air grab samples; however, these air samples are small volume samples collected over a short period of time (one minute) and as a result, interpretation of these data is extremely limited. Ethylbenzene, toluene, and total xylenes were detected in one sample (B-5).

As discussed in Section 2.4.2, the interpretation and application of air grab sample results in understanding potential occupational exposures at OMF South is extremely limited due to the small sample volume (less than one liter) and short sampling duration (one minute). Therefore, Table 3 summarizes air grab sample VOCs results but these results are not discussed in detail.

Methane was not detected in any air grab samples (see Table 4).

2.7 Comparison to Historic LFG Data

Manifold inlet and extraction well sample results from the April 2020 sampling event are compared to the 1988 gas characterization study (Parametrix 1988) and the 1992 source emission evaluation (Am Test-Air Quality Inc. 1992) and are discussed in the following sections to provide insight into changes in concentrations in LFG constituents over the last 25 to 30 years. Average and maximum VOC results for all sampled wells and the manifold inlet are included in Table 5 for comparison to historical data. Table 2 shows the average and range of methane sample results for January 2015 to August 2019 data, along with the April 2020 results for comparison.

2.7.1 VOC and Inorganic Gas Sampling Results (1988 and 1992)

Two historic sources of data on the composition of subsurface gas at the Midway Landfill were identified during the initial document review for the HHRA. These sources include a gas characterization study completed in 1988 as part of the RI and a source emission evaluation completed in 1992 to quantify gas flare emission levels at the Midway Landfill.

As part of the 1988 gas characterization study, gas from individual onsite gas extraction wells was sampled and analyzed for compounds known to be present at specific locations deep within the landfill. In addition, flare inlet gas, representing the combined gas extracted from the numerous individual onsite gas extraction wells, was also characterized to provide a description of the average composition of gas extracted from the landfill (Parametrix 1988).

The 1992 source emission evaluation, conducted by Am Test-Air Quality Inc. to quantify gas combustor emission levels at the Midway Landfill, measured concentrations of VOCs found in pre-combustion flare gas (flare inlet gas) and post-incineration emissions. Subsurface gas extracted from the landfill was sampled during three runs at the inlet and the outlet of one of four LFG combustors to determine the destruction efficiencies for VOCs in LFG.

A number of VOCs were detected in subsurface gas collected from the onsite gas extraction wells and flare inlets in the 1988 and 1992 sampling events.

Concentrations of VOCs detected in subsurface and flare inlet gas during the 1988 gas characterization study were presented in the RI in summary form only (mean and/or maximum concentrations) (Parametrix 1988). Concentrations of VOCs detected in flare inlet gas during the 1992 source emission evaluation were presented for each of the three sample runs. Table 5 presents these data and the April 2020 results in summary (maximum and mean concentrations).

Average VOC concentrations in subsurface and flare or manifold inlet gas combined have decreased since 1988 and 1992 for all detected VOCs. The RI noted that benzene, ethylbenzene, toluene, total xylenes, and vinyl chloride were found most frequently and in the highest concentrations in onsite subsurface gas (Parametrix 1988). Hydrogen sulfide was also detected in onsite subsurface gas in the low parts per million range (Parametrix 1988). Compared to 1988 LFG results, the average concentrations of vinyl chloride, toluene, total xylenes, benzene and ethylbenzene in subsurface gas (LFG extraction wells and manifold or flare inlet combined) have decreased by 98%, 91%, 85%, 52% and 35%, respectively. Hydrogen sulfide concentrations have decreased by 66% since 1988.

When compared to the 1992 flare inlet results, vinyl chloride, toluene, total xylenes, benzene and ethylbenzene concentrations have decreased by 95%, 90%, 95%, 70% and 82%, respectively.

2.7.2 Methane Sampling Results (2015-2019)

LFG monitoring has been conducted at the landfill on a regular basis beginning in 1984. Installation and operation of the LFG extraction system is part of the remedy for the Midway Landfill and monitoring and sampling of the extraction wells is part of the operations and maintenance of the system. The Final HHRA discusses the remedy for the Midway Landfill in more detail (HDR 2020).

LFG is collected from the landfill extraction wells and flares by SPU and analyzed for combustible gas (primarily methane), oxygen, carbon dioxide, temperature, static pressure, and other parameters. SPU provided monthly gas monitoring results for 106 sample locations collected between January 2015 and August 2019 for review as part of the HHRA. These results included methane concentrations for 106 locations within the LFG extraction system (e.g., extraction wells, vacuum manifolds, etc.).

Table 2 summarizes methane results from January 2015 - August 2019 and April 2020 for those extraction wells and the manifold inlet sampled in April 2020. Methane was detected in all extraction wells and manifold inlet samples at concentrations within (near the lower end of) the range of the 2015-2019 data.

3.0 LFG Sampling Findings

The April 2020 LFG extraction system sample results indicate that several VOCs remain in LFG at the site; however, when compared to historical data, the VOCs with the highest concentrations in 2020 (benzene, ethylbenzene, and hydrogen sulfide) have decreased substantially since 1988.

VOC results from the manifold inlet and extraction wells and from co-located wells demonstrate that concentrations can vary significantly by depth and by location throughout the landfill footprint. This variation may be due to differences in underlying waste material and conditions and to differences in the vacuum pressure exerted at these depths and locations.

The sampled extraction wells with the highest concentrations of benzene, ethylbenzene, and hydrogen sulfide include those GW-42S and GW-42D and GW-48S and GW-48D. Sampled extraction wells with the lowest VOCs concentrations include GW-7 and GW-52S.

4.0 HHRA Conclusions

The April 2020 LFG sampling event did not provide any new information that would result in a change in the current CSM included in Appendix A of this addendum and described in detail in the HHRA (HDR 2020). The primary source of COPCs at the site, chemical release mechanisms and environmental transport processes, and potentially complete routes of exposure for specific occupations at the OMF South depicted in the CSM remain the same as those presented in the HHRA (HDR 2020).

As discussed in the HHRA (HDR 2020) and in Section 2.4 of this addendum, samples collected directly from the LFG extraction system are not representative of VOC concentrations in subsurface gas that could pose an unacceptable risk to indoor air quality, and should not be used to quantify occupational exposures and resulting risk. As a result, the April 2020 pre-construction sampling results were not used to identify subsurface soil gas COPCs.

However, because hydrogen sulfide was detected at relatively high concentrations (32,297 µg/m^3 in GW-42S relative to the USEPA VISL of 292 µg/m^3) in LFG samples during the April 2020 sampling event, a toxicity profile for hydrogen sulfide is included in Appendix D. The toxicity profile is a summary of available toxicological information and known health effects for a hazardous substance. Overall, the HHRA findings and conclusions have not changed.

As stated in the HHRA findings, the migration of LFG through the subsurface to indoor and ambient air is currently controlled by the gas extraction system and the landfill cap. Continued operation and maintenance of all components of the remedy (including the gas extraction system and the landfill cap) is required if any portion of the property is sold, leased, transferred, or otherwise conveyed. As a result, it is expected that future development of the OMF South at the Midway Landfill would include a gas extraction system and the landfill cap and other engineered protections to mitigate and monitor vapor intrusion of LFG (including methane) to indoor air.

Appendix B: Well Logs

FMX 77-1550-07(3)

GAS WELL DRILLING LOG

WELL No. 7 Coords. N 11,350 E 9723

Landfill name: MIDWAY LANDFILL GAS MIGRATION CONTROL Date 10-2 & 10-3-85

Time drilling 2:44 PM - 5:30 PM 10-2-85
7:00 AM - 3:27 PM 10-3-85

DESCRIPTION OF DRILLING SPOILS:

Cover soil depth: 1.0'

	Description of Spoils
1-19'	PART. DECOMPOSED BLACK WOOD, PAPER, CLOTH, OCCA. TIRE
19-20	SANDY GRAVEL
20-69'	PART. DECOMP. BLACK WOOD (TO 22' ON 10-2-85)
28'	WET " " "
36'	TIRE REMOVED
63'	STEEL CABLE REMOVED
69'-70'	SANDY CLAY

Total depth of well 70' (Diam. 24")

DRILLING CONDITIONS

(Weather, obstructions, etc.)

Drilling company DBM CONTRACTORS, INC

Drilling equipment HENDERSON LL 100,000 lb TRUCK MTD DRILL; 6" KELLY BAR

Operators names CHUCK FENSTERMACKER, MARVINA OLNEY (OILER)

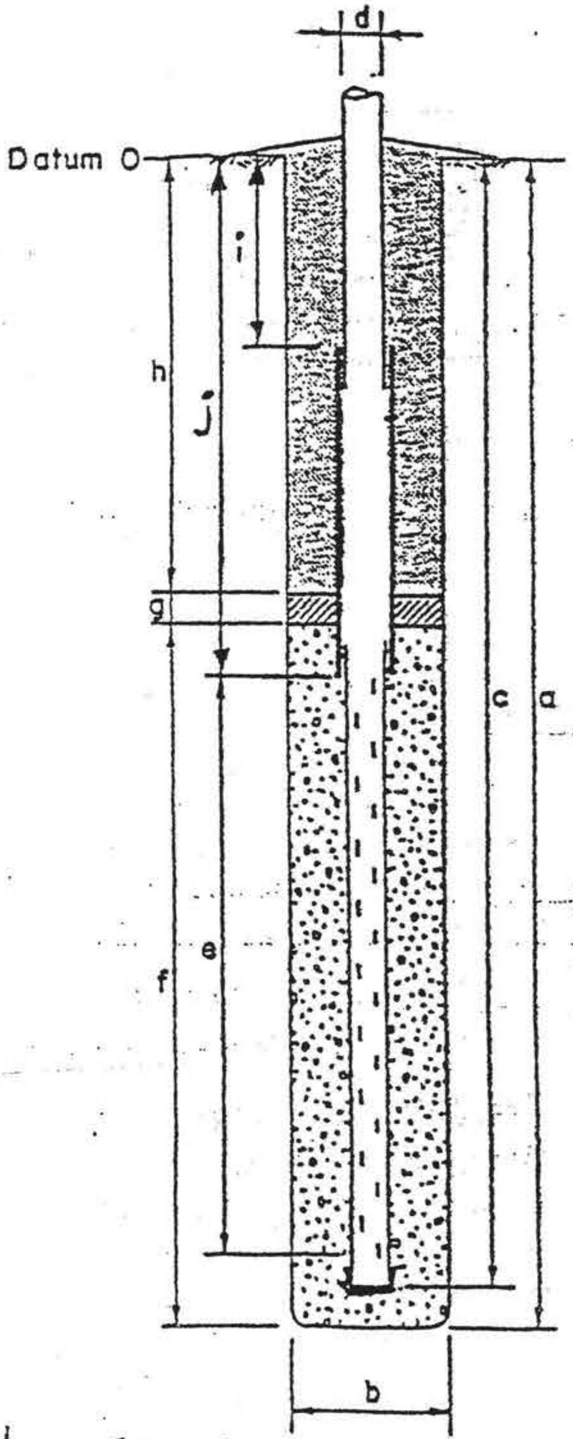
PMX#'5-1550-07(3)

GAS WELL CONSTRUCTION LOG

WELL No. 7 Coord's N 11352 E 9725

Landfill name: MIDWAY GAS MIGRATION Date 10/4/85

I. DIMENSIONS:



a. Total depth of well 76'

b. Diameter of well 24"

c. Well casing interval 68'

d. Diameter of well casing 6"

e. Slotted interval of well casing
from 26' to 68'

f. Permeable material interval 48'

g. Impermeable plug interval 2'

h. Backfill material interval 26'

i. Depth to Top of Slip/Settlement pipe 6'

j. " " Bottom " " " " 26'

II. MATERIALS:

Permeable material 1½" – 3/4" ROUND ROCK

Impermeable plug BENTONITE

Backfill material SILTY CLAY

Casing material (incl. slip joints) 6" & 8" PVC

III. CONSTRUCTION:

Method of placing fill materials: RUBBER TIRE LOADER (CASE 580 BACKHOE, END LOADER)

Method of placing casing: TRUCK MTD HYDRA CRANE

Problems encountered: NONE

PHX 31-1550-14 (18)

GAS WELL CONSTRUCTION LOG

WELL No. 38 Coords N10330.2 E 9864.3

Landfill name: MIDWAY GAS MIGRATION - PHASE II Date ______

I. DIMENSIONS:

a. Total depth of well 112'

b. Diameter of well 24"

LOWER FROM 0 TO 110'
UPPER FROM 0 TO 56'
c. Well casing interval ______

d. Diameter of well casing 6" & 8"

e. Slotted interval of well casing ______
Lower from 68' to 110'
Upper from 26' to 56'

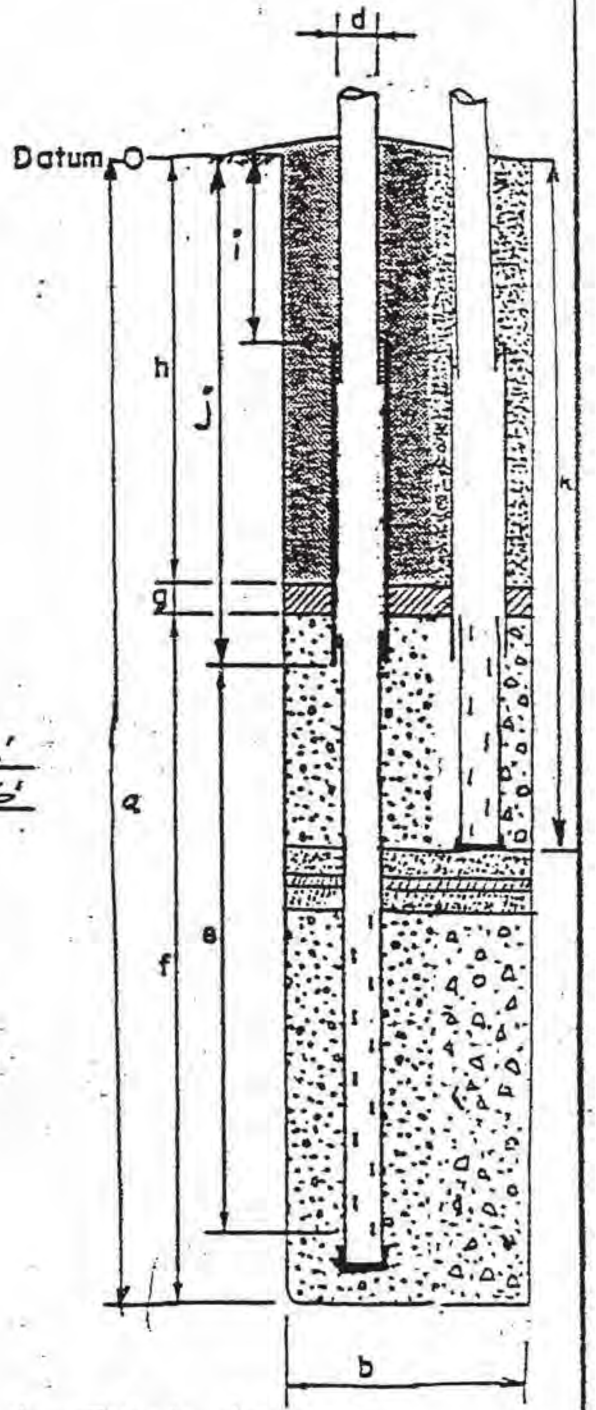
f. Permeable material interval ______
LOWER FROM 64' TO 112'
UPPER FROM 22' TO 58'

g. Impermeable plug interval 2'

h. Backfill material interval 19'

i. Depth to top of slip/settlement pipe 6'

j. " " bottom " / " " " 26'



II. MATERIALS:

Permeable material 1¼" WASHED ROCK

Impermeable plug BENTONITE

Backfill material SILTY CLAY

Casing material (incl. slip joints) SCH. 40 PVC. (6" & 8" DIA.)

III. CONSTRUCTION:

Method of placing fill materials: CAT 931 B TRACK LOADER

Method of placing casing: 30 TON 'LIMA' CRANE w/ 130' TOWER

Problems encountered: ______

GAS WELL DRILLING LOG

Appendix C: QA/QC Review Memorandum and Laboratory

Science & Engineering, Inc.

alta-se.com

988 South Longmont Avenue, Suite 200
Boise, Idaho 83706
Ph: (208) 336-7080; Fax: (208) 908-4980

MEMORANDUM

To:	Sarah Weppner, Alta, Boise
From:	Rachel Gibeault, Alta, Boise
Date:	April 30, 2020
Job Code:	19062-20
Subject:	**QA/QC Review of the April 2020 Sampling of the Tacoma Dome Link Light Rail Data Package**

Section 1 Introduction

This memorandum provides a summary of the third party data validation and data quality assessment performed by Alta Science and Engineering, Inc. (Alta) on the sample results for the additional site characterization efforts conducted by Parametrix for HDR that occurred on April 9, 2020, at the following sample points:

- MAN-1
- MAN-2 (duplicate sample of MAN 1)
- B-2
- B-4
- B-5
- GW-7
- GW-38 (shallow [S] and deep [D] wells)
- GW-42 (S and D)
- GW-48 (S and D)
- GW-52 (S and D)

Sampling procedures and the quality assurance/quality control (QA/QC) review followed guidelines set forth in the following documents:

- *Sampling Instructions for Collecting Samples in Entech Bottle Vacs* (EAS no date) – This sampling procedure is provided in Attachment A. Parametrix followed this sampling procedure in lieu of a Quality Assurance Project Plan (QAPP).
- *National Functional Guidelines for Organic Superfund Methods Data Review* (USEPA 2017a)
- *Guidance for Labeling Externally Validated Laboratory Analytical Data for Superfund Use* (USEPA 2009)
- *USEPA Guidance on Environmental Data Verification and Data Validation* (USEPA 2002)

This memorandum discusses the data quality assessment and data validation performed for the Work Orders listed in Table 1. Data qualifiers used in this review are defined by the U.S. Environmental Protection Agency (USEPA) (2017a).

Table 1. Work Order Data Validation

Laboratory	Work Orders	Analysis	Matrix	Data Validation Level (USEPA 2009)	Review Conducted by
EAS [a]	220163	VOCs [b] CH_4 and CO_2 [c] hydrogen sulfide [d]	Landfill gas and ambient air	Stage 2A	Alta

[a] Environmental Analytical Service, Inc., San Luis Obispo, California

[b] reduced list volatile organic compounds (VOCs) by USEPA Method TO-15 (1999)

[c] methane (CH_4) and carbon dioxide (CO_2) by ASTM D 1945-14 (2019)

[d] by USEPA M16 (2017b)

Section 2 Data Validation and Quality Assessment Summary of Vapor Results

Alta's Stage 2A validation of the analytical data and review of the field data are summarized in Table 2. Procedures/checks that require further discussion are explained below the table, as necessary.

Table 2. Data Quality Review Summary for Indoor Air and Outdoor Air

Data Validation Procedure or Check	Acceptable Frequency? [a]	Acceptable Performance? [a]	Data Qualified?	Discussion Item Number
Sample condition upon receipt at laboratory	--	Y	N	
Preservation	--	Y	N	
Holding times	--	Y	N	
Canister Pressure	--	N	Y	1
Laboratories followed specified analytical methods	--	Y	N	
Method Blanks	Y	Y	N	
Surrogate Recoveries/Deuterated Monitoring Compounds Recoveries (for VOCs)	Y	Y	N	
Laboratory Control Samples	Y	Y	N	
Matrix Spikes	--	--	--	
Laboratory Control Sample Duplicates	Y	Y	N	
Field Blanks	--	--	--	
Field Replicate	Y	N	N	2

[a] Based on professional judgment of the data validator.

-- = not applicable

Discussion Items

1. Canister Pressure - The samples collected by Entech Bottle Vacs (analyzed for VOCs by Method TO-15 [USEPA 1999], for CH_4 and CO_2 by ASTM D 1945-14 [ASTM 2019], and for hydrogen sulfide by USEPA M16 [USEPA 2017b]) had the following pressures in torr. The samples that had no change in torr are rejected (R) based on insufficient volumes: MAN-1, B-2, and GW-52D (as shown below).

Sample ID	Start Time 4/9/2020	Initial Pressure	Final Pressure (Laboratory measured)
MAN-1	08:29	928 torr	928 torr
B-2	09:19	924 torr	924 torr
GW-7	08:38	222 torr	989 torr
GW-38S	08:55	276 torr	884 torr
GW-38-D	08:56	687 torr	886 torr
GW-48S	09:09	508 torr	896 torr
GW-48D	09:11	383 torr	940 torr
B-4	09:57	565 torr	854 torr
GW-52S	09:33	614 torr	882 torr
GW-52D	09:35	871 torr	871 torr
GW-42S	09:42	221 torr	915 torr
GW-42D	09:44	546 torr	944 torr
B-5	10:48	552 torr	857 torr
MAN-2	10:55	689 torr	911 torr

2. Field Replicate – MAN-2 was collected as a field duplicate of MAN-1. However, as mentioned in discussion item 1, the results from MAN-1 were rejected (R) based on insufficient sample canister volume. Therefore, relative percent differences (RPDs) could not be calculated. No data are qualified in the duplicate sample based on precision.

Section 3 Overall Assessment

3.1 Data Accuracy and Precision

Based on this data quality review, Alta determines the laboratory and field data to be of acceptable quality, with the exception of MAN-1, B-2, and GW-52D, which are rejected (R) based on insufficient sample volume.

3.1.1 Accuracy

Alta's Quality Assurance Officer (QAO) did not qualify any data based on accuracy results (surrogate recoveries and laboratory control samples).

3.1.2 Precision

Alta's QAO did not qualify any data based on precision results (laboratory control sample duplicates).

3.2 Data Sensitivity

All laboratory reporting limits were below screening levels.

3.3 Data Usability

Three samples were rejected (MAN-1, B-2, and GW-52D); therefore, the calculated completeness for this sampling event is 79%.

Sampling Instructions for Collecting Samples in Entech Bottle Vacs

ENVIRONMENTAL
Analytical Service, Inc.

Sampling Instructions for Collecting Samples in Entech Bottle Vacs

Please Read The Following Important Information Before Starting

- ***The quick connect on the Bottle Vac is important to hold the Bottle Vac vacuum and protect sample integrity. The Quick Connect Adapter is used to open the Bottle Vac and let sample into the bottle.***
- ***The Bottle Vacs are sent under a vacuum of 29.5" Hg. The vacuum is checked in the laboratory before shipment. If you want to check the vacuum in the field, use a vacuum gauge. Put a Quick Connect Adapter on the gauge to connect to the Bottle Vac.***
- ***Remember that once the Quick Connect Adapter is put on the Bottle Vac Quick Connect, the bottle is open and will begin sampling. If using tubing put the tubing on the Quick Connect Adapter before connecting to the Bottle Vac.***

Bottle Vacs are Silco coated and can be used for both ambient air sampling and source sampling for VOC compounds and hydrogen sulfide. The Bottle Vacs should only be filled to a maximum pressure of 5 psig.

PROCEDURE:

- Remove the Bottle Vac from its box and do a visual check to make sure it is not broken. There should be a Quick Connect Adapter (to 1/4" Swagelok) in the box.

- Any sample tubing or sample port should be connected to the Quick Connect Adapter before the Bottle Vac is connected.

- To sample, connect the Quick Connect Adapter to the Bottle Vac Quick Connect and sample will enter the bottle. The sound of air rushing into the canister should be heard. Leave the Quick Connect Adapter attached for about 1 minute.

- Remove the Quick Connect Adapter to stop sampling. The Quick Connect serves as a valve to hold the sample in the bottle. It does not have to be capped.

- Put the Bottle Vac and Quick Connect Adapter back into the box.

- Fill out Sample Custody Sheet with date, time, location, and any additional information you desire.

- Place Bottle Vac box and custody sheet back into the main box and place the shipping label on the outside of box. Send back UPS. The value of the canisters is $250 each and the client is responsible for the canisters until they are delivered to EAS.

When Done:

Ship the Sampler and Canister back to Environmental Analytical Service, Inc.

Environmental Analytical Service, Inc.

Project Sample Media

SDG Number: 220163

The following sample media was used for this Sample Delivery Group (SDG). The Sample Media column identifies the type of media. For canisters, the Sample Media Batch gives the canister number followed by the cleaning batch number, which is a unique identification. Canisters that are received with sub-ambient pressures are pressurized to about 5 psig. The initial pressure of the canister when it is received is recorded along with the final pressure after pressurization. The canister dilution factor is the ratio of the final to initial pressure. The results are adjusted for the can dilution factor.

SDG	Lab ID	Client Sample No.	Sample Media	Batch	Pressure, torr Initial	Pressure, torr Final	Can Factor
220163	1	MAN 1	259	032420A	928	928	1.00

Laboratory Case Narrative

EAS SDG Number: 220163 **Project Number:** 17510

Client: Parametrix

The Laboratory Case Narrative for the SDG is below. The Chain of Custody form(s) follow the Laboratory Case Narrative.

Sample Control Narrative

The samples were all received in good condition and with proper preservation.

Analytical Methods

The methods used for sample analysis are listed on the Analytyical Report header, and have been modified as described in the EAS Quality Manual..

Case Narrative

QC Narrative

All analyses met EAS method criteria as defined in the Quality Manual, except as noted in the report or QC reports with data qualifiers.

Subcontract Narrative

No sample analysis was subcontracted for this project

Laboratory Certification

I certify that this data package is in compliance with the terms and conditions of the contract, both technically and for completeness other than the condition(s) noted above. The Laboratory Report is property of EAS and its client. The entire report has been reviewed and approved.

Quality Control Report

EAS SDG Number 220163

Project Number: 17510

QC Narrative

Samples were anlayzed in a daily analytical batch (DAB) designated by a QC batch number, and were analyzed using EAS standard laboratory QC specified in the EAS Quality Manual which may be different then the referrenced agency method. Any deviations from the EAS QC criteria are flagged in the Laboratory Control Reports or in the sample Analytical Reports.

Standard Laboratory QC Report

Unless project specific QC was requested, this Section containing the standard laboratory QC (Level 2) supplied with the Analytical Reports. Each sample is analyzed in a Daily Analytical Batch (DAB) which includes the method blank, a laboratory control spike (LCS) and a laboratory control duplicate (LCD). A Daily Analytical Batch QC report is supplied for each method requested.

Method Blank

The method blank is a laboratory generated sample which assesses the degree to which laboratory operations cause a false positive. The target analytes in the analytical reports for a daily analytical batch are "B" flagged if their concentrations are present in the Method Blank above the RL, unless the result is greater then ten times the blank value..

Laboratory Control Spike

A laboratory control spike is a well characterized matrix similar to the sample which is spiked and run in duplicate with each Daily Analytical Batch. The laboratory control spike results are reported as a percent recovery. The QC Criteria for the control spike is listed in the Laboratory Control Report. Any results outside the control limits are flagged with a "Q" on the Laboratory Control Report. The control spike contains an abbreviated list of compounds in the method, and may contain compounds not on the target list for the specified report.

Laboratory Control Duplicate

The laboratory control duplicate is a duplicate analysis of the laboratory control spike, a standard, or a sample depending on the method. The results are reported as a relative percent difference (RPD). The criteria for the duplicate is in the Laboratory Control Report for the Daily Analytical Batch. Any results outside the control limits are flagged with a "Q" on the Laboratory Control Report.

Analytical Reports

EAS SDG Number 220163

Project Number: 17510

The following pages contain the certified Analytical Reports for the samples submitted in the Sample Delivery Group (SDG) and are in order of the EAS Lab ID number. All of the analytical methods used are modifications of the published methods. Procedural method modifications, QC modifications, QC Criteria modifications, target lists, definitions of detection limits, and flags are all explained in detail in the EAS Quality Manual.

The Analytical Report has columns for the method detection limit (MDL), the reporting limit (RL), and the Amount. The Amount is the concentration of the compound in the sample. The report usually has the results reported with two commonly used units. The MDL, RL, and Amount are adjusted for the canister dilution factor and any dilution caused by sample matrix effects.

NELAC CERTIFICATION

EAS is accredited by the National Environmental Laboratory Accreditation (NELAC) with the Florida Department of Health, one of the NELAC certifying states. EAS is certified for the EPA TO-15, EPA TO-11 and EPA TO-4 methods. A list of accredited compounds is available on request.

DETECTION LIMITS

MDL: The MDL is lowest concentration that can be measured to be statistically above the noise level and is determined using the EPA 2016 method which uses the standard deviation of replicate measurements made over time. The method also incorporates systematic instrumentation blank levels. See Quality Manual for detailed explanation.

RL: The reporting limit (RL) is the lowest concentration that can be reliably reported for each compound that meets the QC Criteria for the method, background levels, or project specific considerations. The QC criteria level for the method blank is to be less then the RL See Quality Manual for more information.

DATA FLAGS

In the standard report, if a compound is not detected above the method detection limit, a "ND" is in the Amount column. The flag column is used for both the not detect flag and for any data flags.

B - This compound was detected in the batch method blank above the reporting limit and is greater then one tenth the amount in the sample.

E - This compound exceeds the calibration range for this sample volume.

J - The amount reported is estimated because it was below the RL and could be below the lowest calibration point, have higher uncertainty, or could be the result of system background

UNITS

PPBV or PPMV: Parts-per-billion (or million) by volume is a mole (volume) ratio of the moles of analyte divided by the moles of air (gas). This is the primary unit used to report air or gas concentrations and is independent of temperature and pressure.

UG/M3 OR MG/M3: The reported result was calculated based on 1 atm pressure and a temperature of 25C. The conversion from PPBV is: UG/M3 = PPBV x MW/24.46 where 24.26 is the gas constant and MW is the Compounds Molecular Weight (sometimes called Formula Weight)

Appendix D: Hydrogen Sulfide Toxicological Profile

Toxicological Profile for Hydrogen Sulfide

Hydrogen sulfide is a flammable, colorless gas with a characteristic odor of rotten eggs. In a landfill, anaerobic bacteria produce hydrogen sulfide, along with methane and carbon dioxide, as a byproduct of digestion of waste. Ambient air concentrations of hydrogen sulfide from natural sources range between 0.00011 parts per million (ppm) (0.15332 micrograms per cubic meter [$\mu g/m^3$]) and 0.00033 ppm (0.45997 $\mu g/m^3$). Concentrations of hydrogen sulfide in urban areas are generally less than 0.001 ppm. The general population is primarily exposed to hydrogen sulfide via the inhalation route. Information on the toxicity of hydrogen sulfide in humans comes from case reports, occupational studies, and community studies. The human data suggest that the respiratory tract and nervous system are the most sensitive targets of hydrogen sulfide toxicity. The most commonly reported non-lethal effect found in individuals acutely exposed to high concentrations of hydrogen sulfide is unconsciousness followed by apparent recovery. Although there is an apparent recovery, many individuals report permanent or persistent neurological effects including headaches, poor concentration ability and attention span, impaired short-term memory, and impaired motor functions. Respiratory distress or arrest and pulmonary edema are also associated with exposure to very high concentrations of hydrogen sulfide (about 500 ppm for less than 1 hour). It is believed that these respiratory effects are secondary to central nervous system depression or due to tissue hypoxia. Cardiovascular effects (e.g., irregular heartbeats or abnormally rapid heart rates) have also been observed following an acute exposure to high concentrations of hydrogen sulfide (ATSDR 2016).

Exposure to lower concentrations of hydrogen sulfide can results in less severe neurological and respiratory effects. Reported neurological effects include loss of coordination, poor memory, hallucinations, personality changes and the loss of sense of smell. The respiratory effects include nasal symptoms, sore throat, cough, and difficult or labored breathing (ATSDR 2016).

The reference concentration (RfC) for hydrogen sulfide is $2\text{x}10^{-3}$ milligrams per cubic meter (mg/m^3). The information has been reviewed but a reference dose (RfD) value has not been estimated. Data are inadequate of an assessment of human carcinogenic potential (IRIS 2003).

In the atmosphere, hydrogen sulfide may be oxidized by oxygen and ozone to produce sulfur dioxide, and ultimately sulfate compounds. Sulfur dioxide and sulfates are eventually removed from the atmosphere through absorption by plants, deposition on and sorption by soils, or through precipitation. A residence time of approximately 1.7 days at an ozone concentration of 0.05 mg/m^3 has been calculated for hydrogen sulfide. The lifetime of hydrogen sulfide in air is estimated to range from approximately 1 day in summer to 42 days in the winter (ATSDR 2016).

Operations and Maintenance Facility South

Final Environmental Impact Statement

June 2024

Summary

The following technical report discusses the anticipated construction and operation transportation impacts of the proposed Operations and Maintenance Facility (OMF) South. It meets the requirements of the National Environmental Policy Act (NEPA) and the Washington State Environmental Policy Act (SEPA) to support the OMF South Final Environmental Impact Statement (Final EIS).

This report includes an analysis evaluating the transportation impacts associated with construction and operation of the facility. Impacts are evaluated for multiple modes, including automobile, transit, bicycle, pedestrian, and freight. Operational impacts were forecast based on estimated employee volumes accessing the site during peak travel periods. Each alternative assumes an equal number of employees; however, the built transportation infrastructure, planned jurisdictional improvements, growth projections, acquisitions, preliminary site layouts, and changes to the transportation network resulting from development of OMF South result in different impacts for each site. Construction impacts were qualitatively evaluated based on the number of estimated truck trips as a percentage of daily traffic volumes along anticipated haul routes.

Operational traffic impacts were determined for arterials and local streets by comparing the overall intersection level of service (LOS) for the project alternatives. Impacts would occur if a Build Alternative results in traffic operations performing below the acceptable LOS or volume/capacity (v/c) ratio when the intersection or roadway segment would operate at or above the acceptable LOS or v/c ratio for the roadway under the No-Build Alternative. Impacts may also occur if the build alternative traffic operations reduce the LOS from E to F or if the delay in an LOS F condition is worsened by more than 10 seconds. This approach outlines the process for consideration of mitigation to address possible impacts.

Operational impacts for state highways of statewide significance, such as State Route (SR) 99, would occur if the roadway segment in the build alternatives would increase traffic operations to a LOS E or worse condition when the roadway segment would operate at LOS D or better under the No-Build Alternative. Impacts may also occur if the build alternative traffic operations reduce the LOS from E to F or if the delay in an LOS F condition is worsened by more than 10 seconds. This approach outlines the process for consideration of mitigation to address possible impacts.

For all alternatives, the operational impacts to arterials, local streets, and state highway operations are forecast to be minimal. During the AM peak period, 69 vehicles are forecast to travel to the facility and 11 are forecast to leave it. Similar activity is forecast for the PM peak period, with 57 vehicles leaving the site and zero vehicles arriving. Almost all ingress and egress activity was assumed to occur at a single point for each alternative. The only location forecast to result in impacts is the entrance to the Midway Landfill Alternative at SR 99 and S 246th Street during the AM peak period. These impacts could be mitigated through modifications to the intersection or by allowing employees to access the site through all three access points rather than only two.

During construction, the greatest transportation impacts would be from truck trips to export and import fill material for the Midway Landfill Alternative Hybrid and Full Excavation subsurface construction design options (the Platform subsurface construction design option would keep existing fill in place). The Hybrid subsurface construction design option is estimated to have slightly higher peak daily truck trips than the Full Excavation subsurface construction design option, up to 564 round trip truck trips daily, with site preparation activities lasting up to 5 years and 7 months. These truck trips would range from 7.7 percent to 12.8 percent of existing single-direction traffic along arterials of the anticipated haul route, but up to 22.7 percent of single-direction traffic on I-5 on- and off-ramps. While I-5 and the arterials surrounding the Midway Landfill Alternative should accommodate the additional truck traffic, the number of daily truck trips could exacerbate existing congestion in some locations.

1 INTRODUCTION

1.1 Project Description

Sound Transit proposes to construct and operate an operations and maintenance facility (OMF) in its South Corridor (OMF South) to meet agency needs for an expanded fleet of light rail vehicles (LRVs). The need to expand LRV maintenance capacity was identified in Sound Transit 3: The Regional Transit System Plan for Central Puget Sound (Sound Transit 3). OMF South would be used to store, maintain, and deploy approximately 144 LRVs for daily service. It would provide facilities for vehicle storage, inspections, maintenance and repair, interior vehicle cleaning, and exterior vehicle washing. Additionally, the facility would receive, test, and commission new LRVs for the entire Link light rail system.

OMF South would also be used to accommodate administrative and operational functions, such as serving as a report base for LRV operators. Included is a Maintenance of Way (MOW) building for maintenance and storage of spare parts for tracks, vehicle propulsion equipment, train signals, and other infrastructure, in addition to storage facilities for the entire Link system. Other facility elements would include employee and visitor parking, operations staff offices, maintenance staff offices, dispatcher work stations, an employee report room, and areas with lockers, showers, and restrooms for both operators and maintenance personnel.

Three site alternatives for the OMF South project are evaluated in the Draft Environmental Impact Statement (EIS): two in Federal Way and one in Kent (Figure G1.1-1). These alternatives are named the Preferred Alternative (referred to as the South 336th Street Alternative in the 2021 Draft EIS), the South 344th Street Alternative, and the Midway Landfill Alternative, respectively. Figures G1.1-2 through G1.1-4 show the conceptual site layout for each alternative.

OMF South would need to have tracks connecting to a light rail line that will be operating when the facility is planned to open, which in southern King County is the Federal Way Link Extension (FWLE). The length and location of these connecting tracks varies by alternative. The Preferred Alternative would require the construction of approximately 1.4 miles of mainline tracks and the South 344th Street Alternative would require approximately 1.8 miles of mainline tracks. The Midway Landfill Alternative is adjacent to FWLE and would connect by lead tracks directly to the FWLE mainline tracks. The Preferred and South 344th Street alternative mainlines include tail tracks that extend approximately 1,000 feet past the site to allow trains to turn around and access the site from the south if the northern lead tracks were out of service.

The Preferred and South 344th Street alternative would also include a test track to prepare new vehicles for service. The test track would run east of and parallel to the mainline connecting the sites to FWLE. Figure G1.1-5 shows the mainline track options. The Midway Landfill Alternative would not include a test track because the varying grades of the existing mainline tracks make it infeasible. Due to this, this analysis assumes that LRV testing would occur on the mainline tracks.

In addition to the features identified above, the Preferred Alternative includes the extension of 18th Place S between S 340th Street and S 336th Street to replace the functions of 20th Avenue S, which would be vacated, and the extension of 21st Ave S south to S 344th Street to meet Federal Way code requirements.

1.2 Organization of this Technical Report

In addition to Section 1, Introduction, this report includes the following chapters:

Section 2, Methods and Assumptions, summarizes the analysis methods used to assess the build alternatives in this report, and includes a section on guiding regulations, plans, and policies, including agency participation in the planning and analysis process.

Section 3, Affected Environment, discusses the existing transportation conditions.

Section 4, Impacts, describes:

- long-term impacts on all modes of travel – for the No-Build Alternative and for the build alternatives for the design year (2042)
- expected impacts due to project construction activities
- indirect impacts
- cumulative impacts

Section 5, Potential Mitigation Measures, describes the measures that could be implemented to mitigate the potential effects of the project.

2 APPROACH AND METHODS

The methodology and assumptions used to analyze the transportation impacts for the alternatives are discussed in detail in the Transportation Technical Analysis Methodology Memorandum (Attachment G1-1). The Environmental Methodology Report (Sound Transit 2020a) includes the following information concerning the transportation analysis:

- Summary of the transportation methodology, including study area selection, years of analysis, intersections analyzed, and study time periods
- Description of the relevant policies, laws, and regulations that governed or influenced the transportation analysis
- Description of data collected to establish the affected environment
- Description of the analysis methods (qualitative and/or quantitative) used to assess property access and local circulation, nonmotorized facilities and modes, transit, construction, and safety
- Summary of traffic operations analysis methods, including agency level of service (LOS) thresholds, and analysis tools
- Description of the thresholds used to identify mitigation measures

2.1 Relevant Plans, Policies, and Coordination

2.1.1 Guiding Regulations, Plans, and/or Policies

Analysis of the local transportation impacts was guided by the policy direction established in the numerous plans or policy documents adopted by jurisdictions within the project corridor. These include, but are not limited to:

- Sound Transit 3: the Regional Transit System Plan for Central Puget Sound (Sound Transit 3)
- WSDOT Synchro and SimTraffic Protocol (WSDOT 2018a)
- WSDOT Traffic Analysis Guidebook (WSDOT 2019a)
- City of Kent Transportation Plan (City of Kent 2021) and Federal Way Comprehensive Plan (City of Federal Way 2015) and Capital Improvement Programs (CIPs)

2.1.2 Agency Coordination

The transportation planning and analysis process involved local jurisdictions, state agencies, federal agencies, transit agencies, PSRC, and other interested parties. The cities of Federal Way and Kent were consulted to confirm planned improvements in the study areas.

3 AFFECTED ENVIRONMENT

This chapter discusses the affected environment for the transportation analysis by defining the study area and describing the existing transportation facilities, service types, and conditions in the study areas, including:

- Roadway network (intersections, traffic volumes, and operations)
- Freight
- Transit
- Nonmotorized facilities
- Parking
- Safety

3.1 Study Areas

The focus of the transportation analysis was evaluation of potential operational and construction impacts at the facility, including the traffic activity resulting from employees coming to and departing the site and truck trips and haul routes needed during construction. For the transportation analysis, two study areas were defined: the Preferred and South 344th Street alternatives study area and the Midway Landfill Alternative study area. The study areas are shown in Figures G1.3-1 and G1.3-2.

Due to their close proximity and anticipated impacts to similar intersections, a single study area was identified for the Preferred and South 344th Street alternatives. While the Preferred and South 344th Street study area encompasses several intersections, only those intersections potentially impacted by the Build alternatives were evaluated. The study intersections for the Preferred and South 344th Street alternatives include nine key intersections between SR 99 to the west, I-5 to the east, S 336th Street to the north, and S 344th Street to the south. The study area for the Preferred and South 344th Street alternatives incorporates the area of the mainline in addition to the facility. The elevated mainline track for the Preferred and South 344th Street alternatives would cross several roadways within the study area. Because all of these crossings would be grade separated from the mainline, there would not be impacts to operations.

The Midway Landfill Alternative study area encompasses nine key intersections between SR 99 to the west, I-5 to the east, S 240th Street to the north, and S 260th Street to the south. In response to comments from the city of Kent, intersections #2 through #4 were removed from Section 3.2, Transportation, in the Final EIS because they include commercial driveways on the east side of SR 99 and thus are not subject to the Kent's LOS standards. However, the analysis of these three intersections is retained in this Transportation Technical Report.

The boundaries of the study areas were defined based on the location of potential impacts and in consultation with WSDOT, King County, and the cities of Federal Way and Kent. The approach to the analysis and study areas for each build alternative reflects federal, state, and local laws and regulations. The analysis of transportation impacts associated with construction included the full boundaries of the study area. The analysis of long-term operational impacts from the project is limited to the facilities within the study area that would experience those impacts.

3.2 Arterial and Local Street Operations

3.2.1 Roadway Network

The street network and classifications in the study areas include arterial, collector, and local streets, which are summarized in Tables G1.3-1 and G1.3-2 and Figures G1.3-3 and G1.3-4. Although S 244th Street is located in the city of Des Moines, the intersection of S 244th Street and SR 99, which is one of the intersections evaluated, is located in the city of Kent. All streets in the Preferred and South 344th Street alternatives study area are in the city of Federal Way.

Table G1.3-1 Preferred and South 344th Street Alternatives Study Area Street Network Classifications

3.2.2 Study Intersections

A total of 18 intersections (nine in each study area) were analyzed for this technical report. In the Preferred and South 344th Street alternatives study area, four intersections are located on SR 99. While the Preferred and South 344th Street alternatives study area encompasses many intersections, only those intersections potentially impacted by the Build alternatives were evaluated. The elevated mainline track for the Preferred and South 344th Street alternatives intersects with several roadways within the study area. Because all of these intersections would be grade separated from the mainline, there would not be impacts to operations.

In the Midway Landfill Alternative study area, seven intersections are located on SR 99. In response to comments from the city of Kent, intersections #2 through #4 were removed from Section 3.2, Transportation, in the Final EIS because they include commercial driveways on the east side of SR 99 for which impacts do not need to be evaluated. However, the analysis of these three intersections is retained in this Transportation Technical Report.

The intersections are listed in Tables G1.3-3 and G1.3-4 and are shown in Figures G1.3-5 and G1.3-6. Tables G1.3-3 and G1.3-4 indicate whether the intersection is controlled by a traffic signal or stop signs or whether it is uncontrolled. Intersections with stop signs were all classified as two-way stop controlled (TWSC), meaning that only one street comprising the intersection is stop controlled. There are no intersections that are four-way stop controlled in either of the study areas. Intersections were chosen based on their potential to be directly affected, such as by a change in channelization, signal control, or OMF trips, as well as their potential to be indirectly affected by changes in volume due to trips accessing the system. All intersection peak hour operations were analyzed in the AM and PM peak periods.

Table G1.3-3 Preferred and South 344th Street Alternatives Study Area Intersections

ID	Intersection Location	Existing Control

3.2.3 Traffic Volumes

This section describes the existing AM and PM peak period daily counts as well as weekday turning movement counts at intersections. Daily (24-hour) traffic counts were provided by the cities of Federal Way and Kent. Table G1.3-5 and Table G1.3-6 summarize the average daily traffic volumes. This data informed the decision regarding times to collect turning movement count data for more detailed traffic operations analysis.

Weekday turning movement counts were collected over a 1-day period (September 24, 2019) in the AM peak period between 6 and 9 a.m. and in the PM peak period between 3 and 6 p.m. The turning movement counts included the total number of general-purpose vehicles, medium and large freight vehicles, pedestrians, and bicycles. Additional turning movement counts were collected by the city of Federal Way during the PM peak period between 4 and 6 p.m. on November 16, 2022. Counts were collected at three study intersections in the Preferred Alternative study area: intersection #2 (SR 99/S 336th Street), intersection #4 (SR 99/16th Avenue S), and intersection #7 (SR 99/S 344th Street). Overall, the peak hour intersection volumes were 10 percent lower in 2022 than in 2019, but there were some movements where there were up to 50 more vehicles per hour in 2022 than in 2019. For these movements, the additional volume was added to the 2019 PM peak hour volumes to account for the larger 2022 volumes. This additional volume was distributed through the roadway system as applicable, meaning that this additional volume would not impact every intersection or movement. Volumes between intersections where there are no driveways were also balanced. Figures G1.3-7 and G1.3-8 show existing AM and PM peak hour intersection turning movements for the common peak hours of 7:45 to 8:45 a.m. and 4:30 to 5:30 p.m. for the Preferred and South 344th Street alternatives study area and 7:15 to 8:15 a.m. and 4:30 to 5:30 p.m. in the Midway Landfill Alternative study area.

Table G1.3-5 Preferred and South 344th Street Alternatives Study Area Average Daily Traffic Volumes

DRAFT: For internal discussion only. Not reviewed or approved on behalf of any party.

3.2.3.1 Intersection Operations

Traffic operations are commonly measured using the LOS method, which is defined in terms of average intersection delay on a scale ranging from A to F, depending on the delay conditions at the intersection. LOS A represents the best conditions with minimal delay, and LOS F represents the worst conditions with severe congestion. Two factors determine delay: (1) the capacity of the intersection as defined by the number of lanes, traffic volumes, lane widths, pedestrian volumes, and other features; and (2) signal timing. Capacity, delay, and LOS are calculated for each traffic movement or group of traffic movements at an intersection. The weighted average delay across all traffic movements determines the overall LOS for a signalized intersection.

The LOS at unsignalized intersections that are stop controlled on one or two approaches is also defined in terms of delay, but only for the worst stop-controlled approach, which is typically the minor street. For unsignalized intersections that are stop controlled on each approach, the average intersection delay is reported. The delay thresholds are lowered for stop-controlled intersections because driver behavior considerations make delays at stop-controlled intersections more onerous. For example, at signalized intersections, drivers may relax during the red interval while waiting for the green interval, but drivers on the stopped approach of a stop-controlled intersection must remain attentive to identifying acceptable gaps in traffic. Table G1.3-7 summarizes the criteria used to define LOS.

Table G1.3-7 Average Control Delay Used in Level of Service

LOS[1]	Signalized Intersections (seconds per vehicle)	Unsignalized Intersections (seconds per vehicle)	Traffic Flow Characteristics (seconds per vehicle)
A	< 10	< 10	Virtually free flow; completely unimpeded
B	> 10 and < 20	> 10 and < 15	Stable flow with slight delays; less freedom to maneuver
C	> 20 and < 35	> 15 and < 25	Stable flow with delays; less freedom to maneuver
D	> 35 and < 55	> 25 and < 35	High density but stable flow
E	> 55 and < 80	> 35 and < 50	Operating conditions at or near capacity; unstable flow
F	> 80	> 50	Forced flow; breakdown conditions

Source: Transportation Research Board (2016).

Note:

(1) The LOS criteria are based on control delay, which includes initial deceleration delay, final deceleration delay, stopped delay, and queue move-up time.

Another common method of measuring traffic operations is volume-to-capacity (v/c) ratio, defined as a fraction representing the ratio of traffic volume to the capacity of a given roadway. The v/c ratio is measured on a decimal scale, with 0.0 representing excessive capacity and anything greater than 1.0 representing congestion, where volume has exceeded roadway capacity. A v/c ratio can be calculated for either the intersection as a whole or by approach. Table G1.3-8 shows the relationship between v/c ratio and the aforementioned LOS analysis procedure by average vehicle delay.

Table G1.3-8 Planning and Operational Level of Service

Analysis Procedure	A	B	C	D	E	F
Planning (v/c ratio)	0.00-0.60	0.61-0.70	0.71-0.80	0.81-0.90	0.91-1.00	>1.00
Operational delay (seconds per vehicle)	0-10	10-20	20-40	40-60	60-80	>80

Source: Transportation Research Board (1980, 2016).

An analysis was prepared using Synchro (version 11.1) software for the existing AM and PM peak-hour LOS at signalized and unsignalized intersections and reviewed against LOS or v/c ratio standards to determine whether the intersections operate at an acceptable LOS or v/c ratio. The Highway Capacity Manual (HCM) report from the Synchro software was used to summarize average intersection delay, LOS, and critical queue lengths. The LOS at a signalized intersection was defined in terms of average intersection delay. To provide consistent comparison between build alternatives, the signal timing for the No-Build Alternative and the build alternatives was optimized in the Synchro software to provide optimal levels of delay. Synchro analyzes intersections in isolation and does not take into account downstream congestion. Actual intersection operations may have more delay based on intersection interactions and queuing propagating upstream and downstream between intersections.[1]

Impact Thresholds

Traffic impacts were determined for arterials and local streets by comparing the overall intersection LOS for the No-Build Alternative and the build alternatives. Impacts would occur if the build alternatives would result in traffic operations performing below the acceptable LOS when the intersection or roadway segment would operate at or above the acceptable LOS under the No-Build Alternative. Impacts may also occur if traffic operations under the build alternative reduce the LOS from E to F or if the delay in an LOS F condition is worsened by more than 10 seconds.

Washington State Department of Transportation

For highways of statewide significance, such as SR 99, impacts would occur if the roadway segment in the build alternatives would increase traffic operations to a LOS E or worse condition when the roadway segment would operate at LOS D or better under the No-Build Alternative. Impacts may also occur if the build alternative traffic operations reduce the LOS on highways of statewide significance from E to F or if the delay in an LOS F condition is worsened by more than 10 seconds.

City of Federal Way

Within the Preferred and South 344th Street alternatives study area, the city of Federal Way has adopted the following v/c ratio standards for its street and highway system (City of Federal Way, 2015) for the PM peak hour:

- Signalized intersections outside of the City Center will experience a 1.2 or lower v/c ratio.
- Unsignalized intersections outside of the City Center will experience a 1.0 or lower v/c ratio.
- The City Center area will experience an average of 1.1 or lower v/c ratio.

Federal Way does not have LOS or v/c ratio standards for AM peak period operations. No intersections evaluated as part of this analysis are located in the Federal Way City Center. Figures G1.3-9 through G1.3-12 show existing AM and PM peak hour operations at the study intersections.

---

[1] Uncontrolled intersections were analyzed as TWSC intersections.

City of Kent

Within the Midway Landfill Alternative study area, Kent evaluates LOS at the roadway corridor level. The city of Kent calculates the LOS operation for key corridor intersections (in seconds of delay) during the PM peak period and then calculates an average based on a weighting of the corridor intersection volumes. Kent does not have LOS standards for AM peak period operations. This method provides a corridor-wide result, allowing some intersections to operate at a congested LOS as long as the overall corridor operation is maintained. The city of Kent's adopted LOS standard requires that all corridors operate at LOS E or better during the PM peak hour, with the exception of the Downtown zone, which is allowed to operate at LOS F, and the SR 99 corridor, which must meet WSDOT standards (City of Kent 2021). One intersection, #9 in the Midway Landfill Alternative study area, is located on a key corridor. If operations at this intersection were to degrade below LOS E and change by a full LOS step below the No-Build as a result of the project, the entire corridor would then need to be evaluated. No intersections evaluated as part of this analysis are located in the Kent Downtown zone. For intersections that would operate at LOS F under the No-Build Alternative, impacts would occur if the delay in an LOS F condition is worsened by more than 10 seconds.

3.2.3.2 AM Analysis

The existing AM peak hour LOS and delay for the study area intersections evaluated are shown in Table G1.3-9 and Table G1.3-10. In the Preferred and South 344th Street alternatives study area, all intersections operate at or better than the standards for the roadway. All intersections in the Midway Landfill Alternative study area operate at or better than the standards for the roadway in the AM peak hour. Because Federal Way and Kent's adopted LOS or v/c ratio standards applies only to the PM peak hour, those intersections located in those cities but not on a state highway are exempt from LOS or v/c ratio requirements in the AM peak hour.

Table G1.3-9 Existing AM Peak Hour Traffic Operations for Preferred and South 344th Street Alternatives Study Area Intersections

ID	Intersection	Control Type	Agency (Standard)	AM Peak LOS[1, 2]	AM Peak Delay (seconds)[1, 2]	V/C Ratio[1, 2]
1	S 336th Street/ 20th Avenue S	Signal	N/A	N/A	N/A	0.44
2	SR 99/S 336th Street	Signal	WSDOT Highways of Statewide Significance (LOS D)	D	44	N/A
3	SR 99/S 340th Street	TWSC	WSDOT Highways of Statewide Significance (LOS D)	C	17	N/A
4	SR 99/16th Avenue S	Signal	WSDOT Highways of Statewide Significance (LOS D)	D	35	N/A
5	16th Avenue S/ S 341st Place	TWSC	N/A	N/A	N/A	0.11
6	18th Place S/ S 341st Place	Uncontrolled	N/A	N/A	N/A	0.03
7	SR 99/ S 344th Street	TWSC	WSDOT Highways of Statewide Significance (LOS D)	C	23	N/A

Table G1.3-9 Existing AM Peak Hour Traffic Operations for Preferred and South 344th Street Alternatives Study Area Intersections (continued)

ID	Intersection	Control Type	Agency (Standard)	AM Peak LOS[1, 2]	AM Peak Delay (seconds)[1, 2]	V/C Ratio[1, 2]
8	S 344th Street/ 16th Avenue S	Signal	N/A	N/A	N/A	0.33
9	S 344th Street/ 18th Place S	Uncontrolled	N/A	N/A	N/A	0.03

Notes:

(1) Synchro analyzes intersections in isolation and does not take into account downstream congestion. Actual intersection operations may have more delay based on intersection interactions and queuing propagating upstream and downstream between intersections.

(2) Intersections were analyzed using HCM 6th Edition (Transportation Research Board 2016) for signalized and unsignalized intersections, except where HCM 6th Edition limitations necessitated use of HCM 2000 methodology (Transportation Research Board 2000).

Table G1.3-10 Existing AM Peak Hour Traffic Operations for Midway Landfill Alternative Study Area Intersections

ID	Intersection	Control Type	Agency (Standard)	AM Peak[1, 2, 3] LOS	AM Peak[1, 2, 3] Delay (seconds)
1	SR 99/S 240th Street	Signal	WSDOT Highways of Statewide Significance (LOS D)	C	32
2	SR 99/S 244th Street	TWSC	WSDOT Highways of Statewide Significance (LOS D)	D	31
3	SR 99/Midway Mobile Home Park Driveway	TWSC	WSDOT Highways of Statewide Significance (LOS D)	D	27

5	SR 99/ S 248th Street	TWSC	WSDOT Highways of Statewide Significance (LOS D)	D	33
6	SR 99/ S 252nd Street	Signal	WSDOT Highways of Statewide Significance (LOS D)	A	8
7	SR 99/S 260th Street	Signal	WSDOT Highways of Statewide Significance (LOS D)	D	37
8	29th Avenue S/ S 252nd Street	TWSC	City of Kent (LOS E)	A	9
9	29th Avenue S/ S 259th Street	TWSC	City of Kent (LOS E)	C	21

Notes:

(1) Synchro analyzes intersections in isolation and does not take into account downstream congestion. Actual intersection operations may have more delay based on intersection interactions and queuing propagating upstream and downstream between intersections.

(2) Intersections were analyzed using HCM 6th Edition (Transportation Research Board 2016) for signalized and unsignalized intersections, except where HCM 6th Edition limitations necessitated use of HCM 2000 methodology (Transportation Research Board 2000).

(3) At signalized intersections utilizing HCM 6th Edition methodology, U-turn movements were added to left-turn movements to allow for analysis.

3.2.3.3 PM Analysis

The existing PM peak hour LOS and delay for the study area intersections evaluated are shown in Table G1.3-11 and Table G1.3-12. In the Preferred and South 344th Street alternatives study area, only intersection #2 (SR 99/S 336th Street) operates below standards in the PM peak hour. Volumes along each approach of intersection #2 (SR 99/S 336th Street) are high, and two approaches operate at LOS E (westbound and southbound), while the other two operate at LOS D (eastbound and northbound).

Table G1.3-11 Existing PM Peak Hour Traffic Operations for Preferred and South 344th Street Alternatives Study Area Intersections

8	S 344th Street/ 16th Avenue S	Signal	City of Federal Way (v/c 1.2)	N/A	N/A	0.43
9	S 344th Street/ 18th Place S	Uncontrolled	City of Federal Way (v/c 1.0)	N/A	N/A	0.05

Notes:

(1) Synchro analyzes intersections in isolation and does not take into account downstream congestion. Actual intersection operations may have more delay based on intersection interactions and queuing propagating upstream and downstream between intersections.

(2) Intersections were analyzed using HCM 6th Edition (Transportation Research Board 2016) for signalized and unsignalized intersections, except where HCM 6th Edition limitations necessitated use of HCM 2000 methodology (Transportation Research Board 2000).

(3) Cells highlighted in ***gray bold and italicized*** identify intersections that operate below the LOS standard for the roadway/highway.

In the Midway Landfill Alternative study area, intersection #2 (SR 99/S 244th Street) and intersection #5 (SR 99/S 248th Street) operate below standard in the PM peak hour. The worst movement at both intersections is the northbound left-turn movement, which conflicts with a heavy southbound through volume.

Table G1.3-12 Existing PM Peak Hour Traffic Operations for Midway Landfill Alternative Study Area Intersections

ID	Intersection	Control Type	Agency (Standard)	PM Peak[1, 2, 3, 4] LOS	PM Peak[1, 2, 3, 4] Delay (seconds)
1	SR 99/S 240th Street	Signal	WSDOT Highways of Statewide Significance (LOS D)	D	39
2	SR 99/S 244th Street	TWSC	WSDOT Highways of Statewide Significance (LOS D)	***E***	***41***
3	SR 99/Midway Mobile Home Park Driveway	TWSC	WSDOT Highways of Statewide Significance (LOS D)	B	13
4	SR 99/S 246th Street	TWSC	WSDOT Highways of Statewide Significance (LOS D)	A	0
5	SR 99/S 248th Street	TWSC	WSDOT Highways of Statewide Significance (LOS D)	***E***	***36***
6	SR 99/S 252nd Street	Signal	WSDOT Highways of Statewide Significance (LOS D)	C	26
7	SR 99/S 260th Street	Signal	WSDOT Highways of Statewide Significance (LOS D)	D	44
8	29th Avenue S/S 252nd Street	TWSC	City of Kent (LOS E)	A	9
9	29th Avenue S/S 259th Street	TWSC	City of Kent (LOS E)	D	25

Notes:

(1) Synchro analyzes intersections in isolation and does not take into account downstream congestion. Actual intersection operations may have more delay based on intersection interactions and queuing propagating upstream and downstream between intersections.

(2) Intersections were analyzed using HCM 6th Edition (Transportation Research Board 2016) for signalized and unsignalized intersections, except where HCM 6th Edition limitations necessitated use of HCM 2000 methodology (Transportation Research Board 2000).

(3) At signalized intersections utilizing HCM 6th Edition methodology, U-turn movements were added to left-turn movements to allow for analysis.

(4) Cells highlighted in ***gray bold and italicized*** identify intersections that operate below the LOS standard for the roadway/highway.

3.3 Freight

Freeways, arterials, and local streets are important to moving freight and goods in the study area. Freight is transported only via the roadway network in the study area; no other transportation modes provide freight movement.

WSDOT has designated roadways as freight routes that are classified based on the amount of annual tonnage that is transported along a road in a particular year. This classification system is called the Freight Goods Transportation System. The classifications range from roadways that carry more than 20,000 tons in 60 days to more than 10 million tons annually, as summarized in Table G1.3-13.

Table G1.3-13 Freight Goods Transportation System Classification System

Freight Goods Transportation System Classification	Annual Gross Tonnage
T-1	Over 10,000,000
T-2	4,000,000 to 10,000,000
T-3	300,000 to 4,000,000
T-4	100,000 to 300,000
T-5	Over 20,000 in 60 days

Source: (WSDOT 2020b).

In the study areas, there are several designated freight routes, which include:

- I-5: T-1 route
- SR 99: T-3 route
- 23rd Avenue S: T-3 route
- S 259th Place: T-3 route
- S 260th Place: T-3 route

SR 99 is a designated truck/freight route by the cities of Federal Way and Kent. The city of Federal Way has also designated 16th Avenue S as a freight route.

The primary freight access routes in the study areas are shown in Figure G1.3-13 and Figure G1.3-14.

3.4 Transit

King County Metro Transit (Metro), Sound Transit, and Pierce Transit provide transit service in the study area, with regional and local bus fixed route service to transit centers, park-and-ride facilities, and bus stops.

Nine bus routes provide service to the study areas.[2] Table G1.3-14 summarizes the service provider, route number, weekday frequency, and routing. Figure G1.3-15 and Figure G1.3-16 show the fixed route transit services provided in the study area. In addition to fixed route bus service, Metro also provides paratransit (Access) and various rideshare services, such as vanpool and ride matching services. Neither light rail nor commuter rail service is currently provided in the study areas. Bus stops in the study areas are located primarily on SR 99 but also include some stops on 20th Avenue S, S 336th Street, 16th Avenue S, and at the Federal Way/S 320th Street Park & Ride.

The Federal Way/S 320th Street Park & Ride is located within the Preferred and South 344th Street alternatives study area. It is served by Metro routes 177, 182, 193, and 903 and Pierce Transit routes 402, 500, and 501. Parking is available and free for transit customers. It has 877 spaces and had a utilization rate of 1.3 percent in the first quarter of 2023 (King County Metro 2023).

Table G1.3-14 Study Areas Existing Transit Service

Service Provider	Route	Weekday Frequency	Routing
King County Metro Transit	RapidRide A Line	10–15 minutes all day	Federal Way Downtown Station to Tukwila International Boulevard Station
King County Metro Transit	165	20–30 minutes during the AM and PM peak periods; 30 minutes midday	Green River College to Burien Transit Center via Auburn, Kent, Des Moines, and Normandy Park
King County Metro Transit	177	20–60 minutes during the AM and PM peak periods	Federal Way/S 320th Park & Ride to downtown Seattle
King County Metro Transit	182	20–30 minutes during the AM and PM peak periods; 60 minutes midday	Northeast Tacoma to Federal Way Downtown Station
King County Metro Transit	193	5–90 minutes during the AM and PM peak periods	Federal Way/S 320th Park & Ride to First Hill Seattle via Star Lake, Kent, Des Moines, and Tukwila
King County Metro Transit	903	30–60 minutes all day	Federal Way Downtown Station to Twin Lakes
Pierce Transit	402	30-60 minutes during the AM peak period; 60-80 minutes during the PM peak period and midday	Meridian to Federal Way Downtown Station
Pierce Transit	500	60 minutes all day	Tacoma to Federal Way Downtown Station
Pierce Transit	501	60 minutes all day	Milton to Federal Way Downtown Station

Sources: King County Metro (2023); Pierce Transit (2023).

---

[2] Additionally, several Metro and Sound Transit routes provide service on I-5 through the study areas.

DRAFT: For internal discussion only. Not reviewed or approved on behalf of any party.

OMF South

The city of Federal Way designates transit priority corridors that are welcoming to transit and have appropriate supportive amenities that encourage ridership. SR 99 and 16th Avenue S are transit priority corridors in the Preferred and South 344th Street alternatives study area. The city of Kent does not have designated transit streets or priority corridors.

3.5 Nonmotorized Facilities

In general, the opportunities for nonmotorized (bicycle and pedestrian) circulation in the study areas are limited. East-west circulation within the study areas is limited by the presence of I-5. Each study area has only one crossing of I-5: S 336th Street in the Preferred and South 344th Street alternatives study area and S 259th Street in the Midway Landfill Alternative study area. As a result, most east-west streets in the study areas are dead ends.

In the Preferred and South 344th Street alternatives study area, north-south circulation is provided via SR 99, 16th Avenue S, 18th Place S, 20th Avenue S, and 23rd Avenue S. East-west travel is facilitated by S 324th Street, S 336th Street, S 340th Street, S 341st Place, and S 344th Street.

The presence of the Midway Landfill and other large developments restrict north-south nonmotorized circulation in the Midway Landfill Alternative study area north of S 252nd Street, and SR 99 provides the only north-south pedestrian connection in the study area between S 240th Street and S 252nd Street. The street network south of S 252nd Street has a more developed grid and offers better opportunities for nonmotorized circulation. East-west circulation is similarly restricted.

Nonmotorized facilities are inventoried in the following sections. Figure G1.3-17 and Figure G1.3-18 display the existing pedestrian and bicycle facilities within the study areas and their vicinities.

3.5.1 Pedestrian Facilities

Sidewalks are provided on most arterial streets in the study areas. Exceptions include a portion of the north side of S 336th Street and S 344th Street between SR 99 and 16th Avenue S in the Preferred and South 344th Street alternatives study area as well as a short segment of S 259th Street west of I-5 in the Midway Landfill Alternative study area. Sidewalks are also present on some nonarterial streets in the study areas. Marked crosswalks are provided at signalized intersections in the study areas and provide opportunities to access pedestrian facilities west of the study areas. I-5 restricts most opportunities for pedestrian connections east of the study areas.

3.5.2 Bicycle Facilities

Bicycle facilities in the Preferred and South 344th Street alternatives study area include east- and westbound bicycle lanes on S 336th Street east of 20th Avenue S and a greenway on 20th Avenue S, S 341st Place, 18th Place S, and S 344th Street. The Bonneville Power Administration (BPA) Trail, a shared-use trail, is located to the west of the study area, but there are no dedicated bicycle facilities that provide connections to it. The bicycle lanes on S 336th Street provide connections to facilities east of I-5 on Weyerhaeuser Way S. Federal Way recently installed shared lane markings for bicycles on 25th Avenue S, north of the South 320th Park & Ride.

There are no designated bicycle facilities in the Midway Landfill Alternative study area. Bicycle lanes are on some nearby roadways, and the nearest regional trail is the Green River Trail east of I-5. However, there are no existing bicycle connections from the Midway Landfill Alternative study area to these facilities.

OMF South

3.5.3 Pedestrian and Bicycle Volumes

Along with the weekday turning movement counts, bicycle and pedestrian counts were collected for the same 1-day period in the AM and PM peak period (September 24, 2019). Weather is sometimes a variable for consideration when looking at pedestrian and bicycle counts. On the day of the count, the weather was partly sunny with a high of 70 degrees Fahrenheit; therefore, the weather was conducive to both modes. Tables G1.3-15 through G1.3-18 show the existing AM and PM peak hour bicycle and pedestrian counts at the study area intersections for the common peak hours.

Pedestrian volumes were relatively low in the Preferred and South 344th Street alternatives study area during the AM and PM peak hours. The highest pedestrian volumes in this study area were at intersection #2 in the AM peak hour and intersections #3, #5, and #8 in the PM peak hour. The pedestrian volumes are all within serviceable levels for signalized intersections. As shown in the tables, the highest pedestrian volumes in the Midway Landfill Alternative study area are at intersections #1, #6, and #7 in the AM and PM peak hours.

There were almost no bicycle trips through intersections in either study area, both in the AM and PM peak hours.

Table G1.3-15 Existing AM Peak Hour Pedestrian and Bicycle Volumes for Preferred and South 344th Street Alternatives Study Area Intersections

ID	Intersection	Bicycle Eastbound	Bicycle Westbound	Bicycle Northbound	Bicycle Southbound	Pedestrian East	Pedestrian West	Pedestrian North	Pedestrian South

3.6 Parking

On-street parking is limited in the Preferred and South 344th Street alternatives study area. It is permitted between 8:00 a.m. and 6:00 p.m. on the west side of 18th Place S north of S 341st Place, the north side of S 341st Place, and the south side of S 344th Street east of 18th Place S. It is also permitted along 21st Avenue S subject to weight restrictions. Unrestricted (free, with no time restrictions) on-street parking is permitted on most residential streets south of the landfill property in the Midway Landfill Alternative study area. On-street parking is not permitted on SR 99, S 240th Street, S 259th Street, or S 260th Street, or on 18th Place S south of S 341st Place.

All private parking is associated with businesses in the project area, and there are no pay-for-parking facilities within the project area. Several off-street private business parking lots are available for use by employees and patrons within the study areas.

3.7 Safety

Historical intersection collision data was collected from WSDOT for the 3-year period from January 2016 to December 2018. This data was then reviewed to identify if any of the study area intersections or roadway segments have existing safety concerns that could be exacerbated by the project, as described in the following sections. Sound Transit decided not to update this analysis from the 2021 SEPA Draft EIS as collision rates over 2020 and 2021 are not representative due to the effects of the COVID pandemic. The data from 2016 to 2018 provides a more conservative (higher) collision rate.

3.7.1 Collisions by Severity

Tables G1.3-19 and G1.3-20 summarize collisions by severity and include total collisions and collision rates over the specified 3-year period at both study area intersections and roadway segments.

The majority of collisions at the study intersections and roadway segments resulted in property damage only (nearly 69 percent in the Preferred and South 344th Street alternatives study area and approximately 65 percent in the Midway Landfill Alternative study area). Almost all remaining collisions (approximately 30 percent in each study area) resulted in minor or possible injuries.[3]

In both study areas, no notable contributing factors were provided for the fatal and serious injury crashes other than two due to driver inattention and one due to driver disregard for a traffic signal.

Figure G1.3-19 and Figure G1.3-20 show the location of collisions by severity in the study areas.

Table G1.3-19 Existing Collisions by Severity for Preferred and South 344th Street Alternatives Study Area Intersections and Roadway Segments

---

[3] WSDOT defines minor injury as "One or more persons in a crash had a non-life threatening injury such as: lump on the head, abrasion, bruise, or minor laceration" and possible injury as "One or more persons in a crash had: momentary unconsciousness, claim of injury, limping, complaint of pain, or nausea. These injuries are those reported by the person or indicated by their behavior, but where no wounds or injuries are readily evident" (WSDOT 2020)

Table G1.3-19 Existing Collisions by Severity for Preferred and South 344th Street Alternatives Study Area Intersections and Roadway Segments (continued)

ID	Intersection/ Roadway Segment Name	Intersection/ Roadway Segment Average Daily Traffic	Fatal	Serious Injury	Minor or Possible Injury	Property Damage Only	Total	Collision Rate (collisions/ MEV or MVMT)[1,2]

3.7.2 Collisions by Type

In addition to summarizing the collision data by severity, study area intersection collisions are summarized by type in Tables G1.3-21 and G1.3-22. The most common types of collisions in the study areas were rear-end; angle (T-bone) collisions represented the second most common type of collision. Rear-end collisions made up the highest percentage (approximately 39 percent) of all collisions at intersections and roadway segments on SR 99, while angle collisions made up 21 percent of all crashes in the area.

Table G1.3-21 Existing Collisions by Type (January 2016 to December 2018) for Preferred and South 344th Street Alternatives Study Area Intersections

ID	Intersection/ Roadway Segment Name	Approach Turn	Rear End	Sideswipe	Angle (T Bone)	All Others	Head On	Fixed Object	Bicyclist	Pedestrian	Total

Source: WSDOT Transportation Data and GIS Office, January 2016 to December 2018.

Disclaimer: Under 23 U.S. Code § 409, safety data, reports, surveys, schedules, or lists compiled or collected for the purpose of identifying, evaluating, or planning the safety enhancement of potential crash sites, hazardous roadway conditions, or railway-highway crossings are not subject to discovery or admitted into evidence in a federal or state court proceeding or considered for other purposes in any action for damages arising from any occurrence at a location mentioned or addressed in such reports, surveys, schedules, lists, or data.

Sideswipe collisions made up 16 percent of collisions in both study areas. Of the 12 serious injury or fatality collisions described in Section 3.7.1, eight involved either pedestrians or bicyclists. Collisions occurred in the business access transit (BAT) and high-occupancy vehicle (HOV) lanes in both study areas, although at a much lower rate than those in the innermost lanes. Collision locations by type are shown in Figure G1.3-21 and Figure G1.3-22.

3.7.2.1 Preferred and South 344th Street Alternatives

During the 3-year period (January 2016 to December 2018), no fatal crashes and two serious injury crashes occurred in the Preferred and South 344th Street alternatives study area. A total of 224 collisions occurred at intersections and roadway segments in the study area. The intersection at SR 99/S 336th Street had the highest number of collisions (64), equating to a rate of more than 21 collisions per year. The next highest number of collisions (45) occurred at the SR 99/16th Avenue S intersection, resulting in a rate of 15 collisions per year. Collisions at these two intersections comprise almost 49 percent of the total collisions in the study area. Collisions on SR 99 and 16th Avenue S accounted for more than 75 percent of all roadway segment collisions in the study area. Rear-end and sideswipe collisions accounted for more than 56 percent of all collisions on roadway segments in the study area. The numbers of angle (T-bone) collisions and rear-end collisions were almost the same. Bicyclists and pedestrians were involved in four collisions each. One of the two serious injury collisions in the Preferred and S 344th Street Alternatives study area involved a bicyclist.

Three collisions involving buses occurred in the Preferred and South 344th Street Alternatives study area. They include one involving a school bus at the SR 99/S 344th Street intersection and two involving transit buses at the SR 99/16th Avenue S and SR 99/S 336th Street intersections. The three collisions were rear-end, angle, and approach-turn collisions, respectively. One of the bus collisions resulted in minor injuries, and the other two bus collisions had no injuries.

In the Preferred and South 344th Street Alternatives study area, 19 collisions occurred in the SR 99 HOV lane, representing 30 percent of all roadway segment collisions.

The city of Federal Way has established collision rate thresholds, defined in their *Public Works Development Standards Manual* (City of Federal Way 2019). Four intersections in the Preferred and South 344th Street Alternatives study area, three of which are along SR 99, exceed the intersection collision rate threshold of one collision per million entering vehicles (see Table G1.3-20). No roadway segments in the study area exceed the segment collision rate threshold of 10 collisions per million vehicle miles traveled. Locations exceeding these thresholds may indicate safety inadequacies as well as prioritized locations for safety improvements.

3.7.2.2 Midway Landfill Alternative

During the 3-year period (January 2016 to December 2018), four fatal crashes and six serious injury crashes occurred in the Midway Landfill Alternative study area. Of these, two fatal crashes and two serious injury crashes occurred at the intersection of SR 99 and S 240th Street. A total of 261 collisions occurred at intersections and roadway segments in the Midway Landfill Alternative study area. The intersections at SR 99/S 240th Street and SR 99/S 260th Street had the most collisions over the 3-year period, with 56 and 57 collisions, respectively, equating to a rate of approximately 19 collisions per year at each intersection. The intersection at SR 99/S 252nd Street had the next highest number of collisions (47) and a rate of approximately 16 collisions per year. Collisions at these three intersections comprise 61 percent of the total collisions in the study area. SR 99 between S 240th Street and S 260th Street had the most roadway segment collisions (63) and a rate of approximately 21 collisions per year. Two collisions involved a bicyclist, and 12 involved a pedestrian.

One collision in the Midway Landfill Alternative study area involved a school bus. It occurred along the S 260th Street roadway segment (SR 99 to 29th Avenue S) and resulted from a sideswipe collision.

Eleven collisions occurred in the SR 99 HOV lane, representing 17 percent of total collisions along roadway segments in the Midway Landfill Alternative study area.

4 TRANSPORTATION IMPACTS

This chapter discusses impacts for the future forecast year of 2042 for the No-Build Alternative and the build alternatives.

4.1 No-Build Alternative

Under the No-Build Alternative, impacts to transportation from construction or operation of OMF South would not occur. However, for the purposes of this Final EIS, the No-Build Alternative assumes that, by the design year 2042, all planned Sound Transit 3 projects, including FWLE and the Tacoma Dome Link Extension (TDLE; currently under environmental review), are built along with the other public and private projects planned within the study area. The proposed alignment for the TDLE mainline track overlaps with the OMF South Preferred and South 344th Street alternatives. If TDLE is constructed as proposed, the mainline track associated with these alternatives would be built later in time. Impacts associated with construction of the mainline track are addressed within the build alternatives impacts discussion below. All other TDLE-related impacts are addressed in Chapter 4 Cumulative Impacts.

4.1.1 Arterial and Local Street Operations

4.1.1.1 Roadway Network and Intersection Modifications

Sound Transit reviewed agency and jurisdictional long-range plans to identify planned and funded transportation projects. The following list of future projects was developed through coordination with WSDOT, city of Federal Way, and city of Kent staff. Very few improvements are planned by the cities of Federal Way and Kent that would alter the roadway network and intersections in the study area for the No-Build Alternative. The following projects are planned by the city of Federal Way in the Preferred and South 344th Street alternatives study area. Only the first project listed has secured funding.

- Add a southbound auxiliary lane on 16th Avenue S from S 344th Street to S 348th Street (the auxiliary lane from S 347th Street to S 348th Street is complete).
- Extend 20th Avenue S to S 344th Street

In the Midway Landfill Alternative study area, the following projects are planned by the city of Kent. Only the first project listed has secured funding.

- Construct two new streets, 32nd Avenue S from S 240th Street to S 244th Street and S 244th Street from SR 99 to 32nd Avenue S, including sidewalks and bike lanes
- Change the signal phasing at the S 260th Street/SR 99 intersection to include flashing yellow arrows on the eastbound and westbound approaches as part of FWLE
- Change the signal phasing at the S 240th Street/SR 99 intersection
- Add westbound dual left-turn lanes and an eastbound right turn pocket at the S 260th Street/SR 99 intersection

4.1.1.2 Traffic Volumes

Future (2042) no-build volumes at the study intersections were forecast using growth rates specific to both Federal Way and Kent. For the Preferred and South 344th Street alternatives study area, a singular growth rate of 0.8 percent per year, consistent with assumptions used for analyzing traffic impacts associated with TDLE was applied to existing volumes. For the Midway

Landfill Alternative study area, growth rates of 1.11 and 1.12 percent per year derived from the FWLE Final Environmental Impact Statement (Sound Transit 2016) were applied to AM and PM peak hour existing volumes, respectively.

Traffic volumes are forecast to increase throughout the study area between existing conditions and the 2042 AM and PM peak hours. Figure G1.4-1 and Figure G1.4-2 show the forecasted 2042 AM and PM peak hour turning movements under the No-Build Alternative.

Intersection Operations

The traffic operations analysis compares the No-Build Alternative at the same study intersections analyzed under existing conditions. The existing and No-Build Alternative AM and PM peak hour LOS and delay for the study area intersections evaluated are shown in Tables G1.4-1 through G1.4-4. Figures G1.4-3 through G1.4-6 show 2042 AM and PM peak hour operations at the study intersections under the No-Build Alternative.

2042 AM Analysis

As shown in Figure G1.4-1 and Table G1.4-1, no intersections in the Preferred and South 344th Street alternatives study area are forecast to operate below the LOS or v/c ratio standards for the roadway during the 2042 AM peak hour for the No-Build Alternative.

As shown in Table G1.4-2, intersection #2 (SR 99/S 244th Street), intersection #3 (SR 99/Midway Mobile Home Park Driveway), and intersection #5 (SR 99/S 248th Street) in the Midway Landfill Alternative study area are forecast to operate below the LOS standards for the roadway during the 2042 AM peak hour for the No-Build Alternative due to increased congestion in 2042 compared with existing conditions. These intersections would experience an increase in delay of 12, 11, and 20 seconds per vehicle compared to the existing condition, respectively. The delays can be attributed to the expected population and employment growth in Kent and surrounding cities. In 2042, some intersections operate with a decrease in delay compared with existing conditions. This could happen because of signal optimization, addition of a municipal project, or a combination of the two.

2042 PM Analysis

As described for the 2042 AM peak hour, the No-Build Alternative would experience more congestion in 2042 than under existing conditions. This can be attributed to expected population and employment growth in Federal Way, Kent, and other nearby communities. For similar reasons as outlined for the morning traffic operations, some intersections will show an operational improvement compared with existing conditions in both study areas.

In the Preferred and South 344th Street alternatives study area, intersection #2 (SR 99/S 336th Street) would experience a decrease in delay from 58 seconds to 54 seconds during the 2042 PM peak hour and would no longer operate below the LOS or v/c ratio standards for the intersection. Despite an increase in volume between existing and 2042, there is a decrease in delay due to signal timing optimization. During the 2042 PM peak hour, two of the Midway Landfill Alternative study area intersections are forecast to operate below the LOS standards for the study area. Intersection #2 (SR 99/S 244th Street) and intersection #5 (SR 99/S 248th Street) would experience increases in delay of 81 and 61 seconds, respectively.

Table G1.4-3 and Table G1.4-4 show the intersections that are forecast to operate below the LOS or v/c ratio standards, as applicable.

Notes:

(1) Synchro analyzes intersections in isolation and does not take into account downstream congestion. Actual intersection operations may have more delay based on intersection interactions and queuing propagating upstream and downstream between intersections.

(2) Intersections were analyzed using HCM 6th Edition (Transportation Research Board 2016) for signalized and unsignalized intersections, except where HCM 6th Edition limitations necessitated use of HCM 2000 methodology (Transportation Research Board 2000).

2042 No-Build Alternative PM Peak Hour Traffic Operations
Midway Landfill Alternative

OMF South

DRAFT: For internal discussion only. Not reviewed or approved on behalf of any party.

4.1.2 Freight

Under the No-Build Alternative, freight traffic is expected to be affected similarly to general-purpose traffic. Freight would experience the same levels of delay as general-purpose traffic on roadways and at intersections with increased congestion.

4.1.3 Transit

In the No-Build Alternative, Link light rail service will extend to Tacoma through the study areas, as well as to downtown Redmond, downtown Seattle, West Seattle, Ballard, University District, Northgate, Lynnwood, Everett, south Kirkland, and Issaquah. As described in Metro's Long Range Plan, Metro Connects, some additional bus service is planned along 16th Avenue S in the Preferred and South 344th Street alternatives study area. Bus service on the north end and south boundaries of the Midway Landfill Alternative study area is expected to increase with the opening of the Kent/Des Moines station near Highline College as part of FWLE (King County Metro 2021). No additional service is planned on SR 99. The bus stops at S 240th Street and SR 99 may be closed, with new RapidRide stops developed at the Link station. Metro plans to provide less peak-oriented bus service on I-5 through the study areas in 2042.

It is assumed Sound Transit will reduce bus service levels on I-5 through the study areas in 2042, as Link light rail will replace much of the current north-south service from south Puget Sound cities to downtown Seattle and the University District. Existing Sound Transit routes that currently provide service to cities north of Tacoma will be truncated at the Tacoma Dome and Fife Link stations, where riders will transfer to or from Link. It is also assumed Pierce Transit will truncate bus service via Routes 402 and 500 at the South Federal Way Link station, and this service would no longer be provided in the Preferred and South 344th Street alternatives study area. Route 501 will be discontinued and no longer provide service in the Preferred and South 344th Street alternatives study area.

Under the No-Build Alternative, Sound Transit would not have the capacity to receive, test, commission, store, maintain, and deploy the expanded fleet of LRVs needed to support existing and planned future expansions of the Link light rail system at planned service levels. As a result, light rail operations would be less efficient than they would otherwise be with the facility, and Sound Transit would not be able to meet the expected ridership demand.

4.1.4 Nonmotorized Facilities

In the No-Build Alternative, pedestrian and bicycle facilities would be improved in accordance with adopted local plans. The Transportation Element of the Federal Way Comprehensive Plan calls for installation of bicycle lanes on S 336th Street between SR 99 and 20th Avenue S and planned trails through the Federal Way/S 320th Street Park & Ride.

Nonmotorized volumes are expected to increase in the Midway Landfill Alternative study area as a result of land use regulations that encourage mixed uses and higher residential densities in the city of Kent's Midway Subarea. The Midway Subarea is located in the western portion of Kent and is bound to the north by SR-516 (Kent-Des Moines Road), to the south by South 272nd Street, and by the City of Des Moines along the entire western border. The Midway Subarea Plan (City of Kent 2011) envisions an expanded, conceptual pedestrian and bike path framework in the study area, including a bridge over I-5 near S 240th Street and a north-south path connecting S 244th Street to S 252nd Street. 29th Avenue S, S 244th Street, S 252nd Street, S 259th Street, and S 260th Street are envisioned as complete streets, meaning that they would add pedestrian and bicycle facilities.

The city of Kent Transportation Master Plan identifies recommended LOS thresholds for pedestrian and bicycle facilities. The city's Pedestrian LOS guidelines describe the comfort of someone walking, which can vary depending on the roadway type and land use context of a given street. Bicycle Level of Traffic stress (LTS), which provides a framework for planning bikeway facilities to meet the needs of their intended users, is used to define treatment options on corridors in the city. Table G1.4-5 summarizes the recommended LOS for existing and planned pedestrian and bicycle facilities in the Midway Landfill Alternative study area.

Table G1.4-5 Recommended Bicycle and Pedestrian LOS Standards for Nonmotorized Facilities in the Midway Landfill Alternative Study Area

Segment	Pedestrian LOS	Bicycle LOS/LTS
SR 99 – S 240th Street to 1st driveway south of S 244th Street	Downtown/TOD Standard	LOS 1
SR 99 – 1st driveway south of 244th Street to S 259th Street	Areas of High Pedestrian Activity	LOS 1
S 259th Street – SR 99 to West Hill Mobile Manor Driveway	Areas of High Pedestrian Activity	LOS 1
S 259th Street – West Hill Mobile Manor Driveway to East Midway Landfill Alternative Study Area Limits	Other Arterials	LOS 1
S 240th Street – SR 99 to just west of I-5	Downtown/TOD Standard	LOS 2
S 252nd Street from SR 99 to 29th Avenue S	N/A	LOS 2
29th Avenue S from 252nd Street to S 259th Street	N/A	LOS 2
S 244th Street from SR 99 to just west of I-5	N/A	LOS 2
32nd Avenue S from S 240th Street to S 244th Street	N/A	LOS 2

Source: City of Kent Transportation Master Plan (2021)

Notes: LTS 1 facilities are very low stress: they are intended to be welcoming to cyclists of all abilities and levels and generally include separated facilities, such as off-street trails or leverage low-speed, low-volume residential streets. The next level of accommodation is LTS 2, which is the category that describes most cyclists, and generally can be met by installing striped or buffered bike lanes on lower speed arterials and collectors.

4.1.5 Parking

In the No-Build Alternative, the quantity of on-street parking along streets within the study areas described in Section 3.6 is not assumed to change. On-street parking use is expected to stay the same as well because the land uses within the study areas are not expected to change (the comprehensive plans for Federal Way and Kent show the underlying zoning remaining the same). Any new developments within the study areas would be expected to provide adequate off-street parking for their use.

4.1.6 Safety

As noted in the Arterials and Operations section, traffic and nonmotorized volumes in the study area are expected to increase by 2042. This could increase collision frequencies for both motor vehicle and nonmotorized users in the study area. The planned roadway and intersection projects previously described could improve safety through rechannelization, improved sight lines, or the addition of turn lanes. The construction of new bicycle and pedestrian facilities would improve safety for nonmotorized users and motor vehicles in the study area. Dedicated pedestrian and bicycle facilities would improve predictability at conflict points between motor vehicles, pedestrians, and cyclists, and would reduce the likelihood of collisions because potential conflict points would be clearly identifiable by all users.

4.2 Long-Term Impacts

4.2.1 Long-Term Impacts Common to all Build Alternatives

This section analyzes the operational impacts common to all the build alternatives within the study areas for the 2042 forecast year. In both study areas, all track crossings of existing or planned roadways would be grade separated. Because there would be no impacts to traffic operations, these track crossings were not included in the intersections evaluated in this analysis.

For each alternative, all access points to the OMF South sites would be controlled by fenced rolling gates, one of which would be located at a guard house. Access to the OMF South site would be granted via approval by staff stationed at the guard house or by an automated system, such as electronic key cards.

The gate operations were evaluated for two scenarios. The first scenario assumed free-flow movement into each OMF South site without considering the effect of opening and closing the rolling gate. The second scenario assumed that the gates open and close between vehicles entering the site. For the second scenario, the capacity for vehicles to enter the gate was calculated based on estimated timing for each gate opening and closing. The second scenario was assumed to represent a more conservative approach with the potential for greater traffic impacts. These impacts are discussed in Section 4.2.1.2, Gate Operations.

This evaluation was completed without the use of the Synchro software because staffed guard houses and gate operations cannot be evaluated with the software. The two scenarios were evaluated to help understand whether there would be operational flexibility at the gates through the peak hour. The peak hour vehicle trips generated at the facility were assigned to study area roadways and intersections based on existing travel patterns. Traffic volumes are forecast to increase throughout the study areas during both the 2042 AM peak hours and the 2042 PM peak hours. An estimated 610 people would be employed at the facility over the course of three shifts. Within the individual shifts, staff would access the facility during various times. Table G1.4-6 details the estimated staff levels for OMF South, maintenance of way (MOW), and Link System-Wide Storage facilities across three shifts. All employees were assumed to arrive in single-occupancy vehicles.

Table G1.4-6 OMF South, MOW, and Link System-Wide Storage Facility Staffing Calculations

	Day	Swing	Graveyard	Total
	3:30 a.m. to 4 p.m.	11 a.m. to 11:30 p.m.	6:30 p.m. – 7:30 a.m.	
Staff Totals	250	195	165	610

All trips forecast to and from the facility were assumed to be single-occupancy vehicle trips. No transit or nonmotorized trips were assumed.

4.2.1.1 Traffic Volumes

The system peak hours used for analysis in the cities of Federal Way and Kent are summarized in Table G1.4-7 and are consistent with existing data trends.

Table G1.4-7 System Peak Hours for the Cities of Federal Way and Kent

	AM Peak Hour	PM Peak Hour
Federal Way	7:45-8:45 a.m.	4:30-5:30 p.m.
Kent	7:15-8:15 a.m.	4:30-5:30 p.m.

Based on the shift times provided for the staffing as shown in Table G1.4-6, there would be overlap among employees from different shifts arriving and departing the site. There are several overlapping shifts throughout the day, with the largest number of inbound and outbound employee trips during midday. A portion of the day and graveyard shifts staffing estimates would apply to the AM and PM peak hour analyses. Due to the staggered arrival and departure times within the shifts, only 69 of the 250 day-shift employees would arrive during the AM peak hour. The overlap of shifts would also result in 11 departures during the AM peak hour. During the PM peak hour, 57 employees are forecast to depart, with no arrivals forecast. Because each employee is assumed to arrive or depart in a single-occupancy vehicle, forecast auto volumes match the employee arrival and departure activity. The amount of freight traffic to and from the OMF South site is anticipated to be minimal, particularly during the AM and PM peak hours, because deliveries would primarily occur during off-peak hours. Therefore, freight traffic was not factored into the analysis. Auto volumes for the build alternatives during the 2042 AM and PM peak hours are shown in Table G1.4-8.

Table G1.4-8 Forecast Auto Volumes for the Build Alternatives 2042 AM and PM Peak Hours

	Inbound AM	Inbound PM	Outbound AM	Outbound PM
Preferred and South 344th Street Alternatives	69	0	11	57
Midway Landfill Alternative	69	0	11	57

4.2.1.2 Gate Operations

As noted previously, the first gate operation scenario assumed free-flow movement into each site. Therefore, no additional queueing and delays would result at the gates, and no spillback from the gates would occur that could impact intersection operations.

The second scenario assumed the rolling gate would open and close for each vehicle. Example calculations for the time required for the gate to open and close and the associated vehicles per hour capacity are shown in Table G1.4-9. Assuming that 75 percent of inbound and outbound vehicles arrive at gate-managed driveways during a peak 15-minute period either before shift change (AM peak hour) or after shift change (PM peak hour), the access gates should have sufficient capacity to accommodate the inbound and outbound vehicles trips without additional queueing and delays that would impact intersection operations.

However, if the time to open and close the gate or the percentage of inbound and outbound vehicles arriving during a peak 15-minute period is larger than assumed, spillback from the gates could occur and the actual intersection delay and queueing could be worse than reported below. Depending on the location of the gate, the driveway could potentially accommodate some number of queuing vehicles.

Table G1.4-9 Forecast Gate Capacity

Alternative	Time Required	Gate Capacity (vehicles/ 15 minutes)	Inbound Vehicles Using Gate Accesses	Outbound Vehicles Using Gate Accesses
Preferred Alternative	15 seconds	60 vehicles	52	43
South 344th Street	15 seconds	60 vehicles	52	43
Midway Landfill	15 seconds	60 vehicles	39	30

Note:
(1) Vehicle volumes at SR 99 Midway gate access represent the vehicles using SR 99/S 246th Street entrance, as vehicles using the S 248th Street entrance would not use the gate.

4.2.1.3 Freight

The build alternatives are not anticipated to negatively affect truck circulation or truck routes on the local street network in the study area. There are no at-grade light rail track profiles that would result in additional crossings or delays for trucks. Freight would experience the same levels of delay as general-purpose traffic on roadways and at intersections throughout the study area.

4.2.1.4 Transit

It is assumed the bus service network under the build alternatives would be the same as the No-Build Alternative, which includes the transit service modifications planned in conjunction with FWLE and TDLE. Additional bus service levels or rerouting to the facility are not anticipated for any alternatives.

Development of OMF South would provide Sound Transit with additional capacity to receive, test, commission, store, maintain, and deploy an expanded fleet of LRVs for planned Link service. This capacity would provide for more efficient operations of existing and planned future expansions of the Link light rail system than would occur without the facility.

4.2.1.5 Parking

Under the build alternatives, existing off-street parking associated with property acquisitions would be removed in order to accommodate development of the facility. For the build alternatives, on-street parking would be eliminated as follows:

- South 344th Street Alternative: 21st Avenue S and S 341st Place, east of 18th Place S, and S 344th Street east of 21st Avenue S
- Midway Landfill Alternative: S 252nd Street

The loss of on-street parking in the study areas is likely to result in minimal impacts. Off-street parking that would be lost would be associated with property acquisitions. The loss of on-street parking on S 252nd Street under the Midway Landfill Alternative could impact adjacent single-family residences; however, there appears to be available capacity along the roadway.

It is estimated that up to 480 spaces will be needed for on-site parking for employees, visitors, and nonrevenue vehicles. Table G1.4-10 summarizes the estimated on-site parking need for employees, visitors, and nonrevenue vehicles. The estimated employee vehicle parking was calculated as the total number of employees during the largest shift plus 50 percent. The day shift is forecast to be the largest shift for the MOW and Link System-Wide Storage.

The conceptual layouts for each alternative (see Figures G1.1-2 through G1.1-4) identify sufficient on-site parking to accommodate forecast demand.

Table G1.4-10 Estimated On-Site Parking Needed for Build Alternatives

	Estimated Parking Need
OMF Building Parking	
OMF Building Day Shift Staff Total + 50%	210
Visitor Spaces	16
Accessible Spaces	6
Motorcycle Spaces	8
Nonrevenue Vehicle Spaces	18
Total OMF Building Parking	**258**
MOW and Facilities Building Parking	
MOW and Facilities Building Day Shift Staff Total + 50%	149
Visitor Spaces	12
Accessible Spaces	4
Motorcycle Spaces	5
Nonrevenue Vehicle Spaces	23
Total MOW and Facilities Building Parking	**193**
Link System-Wide Storage Building Parking	
Link System-Wide Storage Building Day Shift Staff Total + 50%	14
Visitor Spaces	4
Accessible Spaces	2
Motorcycle Spaces	1
Nonrevenue Vehicle Spaces	9
Total Link System-Wide Storage Building Parking	**30**
Total Site Parking	**480**

Note:

(1) Employee and visitor parking includes accessible spaces.

4.2.1.6 Safety

As with the No-Build Alternative, traffic and nonmotorized volumes in the study area are forecast to increase by 2042, which could increase collision frequencies for both motor vehicles and nonmotorized users in the study area. The roadway, intersection, and nonmotorized improvements identified under the No-Build Alternative, and applicable for the build alternatives, would improve safety for motor vehicles and nonmotorized users in the study areas under the build alternatives. OMF South would not result in any adverse safety impacts to intersections, including those with over one crash per million entering vehicles.

With the exception of site driveways, OMF South would be located outside transportation facilities, including roadways, highways, sidewalks, bicycle lanes, and nonmotorized trails. All tracks connecting to the site would be elevated over transportation facilities and would not present conflicts for drivers, buses, freight, pedestrians, or cyclists. All vertical support elements, such as walls and columns, would be sited to comply with transportation safety requirements for fixed objects, vertical and horizontal clearances, and other infrastructure-related safety elements.

4.2.2 Preferred Alternative

4.2.2.1 Roadway Network and Intersection Modifications

The roadway network would be modified for the Preferred Alternative. The alternative would not interfere with the potential to add a southbound auxiliary lane on 16th Avenue S (described above under the No-Build Alternative).

The Preferred Alternative would have three access points, all of which would be provided on S 341st Place. The first would be a visitor/employee entrance with a guard house east of 18th Place S. The current proposal is for all employees to access the site at this location. Access would allow for left-in, left-out, right-in, and right-out at S 341st Place. The second access would be provided 270 feet west of 21st Avenue S and would be used primarily for truck deliveries to the Link System Wide Storage building. The third entrance would be located 120 feet west of 21st Avenue S and would provide access to the MOW building. The second and third entrances would not be used for daily employee access to the site. There would be no turn restrictions at the second or third driveway locations.

The segment of 20th Avenue S from S 336th Street to S 341st Place would be closed. A new roadway would be constructed to the west of the OMFS, extending 18th Place S to S 336th Street. This extension of 18th Place S would add a new three-legged intersection to the south side of S 336th Street. This new S 336th Street/18th Place S Extension intersection would be a TWSC intersection with access for left-in, left-out, right-in, and right-out. Also, 21st Avenue S would be extended to S 344th Street. Development of the Preferred Alternative would not preclude extension of 20th Avenue S from S 341st Place to S 344th Street by the city of Federal Way (described above under the No-Build Alternative).

4.2.2.2 Traffic Volumes

To develop traffic volumes for the Preferred Alternative, existing trips from properties that would be acquired were removed and existing trips that would be rerouted due to changes in the roadway network were rerouted to other intersections or intersection movements. Existing trips from properties that would be acquired were estimated based on existing land uses and estimated trip generation and were confirmed with existing intersection volumes. After removing the existing trips from properties that would be acquired, the majority of the remaining trips that currently use 20th Avenue S are assumed to travel to and from Ellenos Yogurt. It is assumed that existing trips that currently travel to and from Ellenos Yogurt from north of the site would use SR 99 instead of the new 18th Place S Extension due to the character and speed of SR 99. This assumption is conservative and represents worst case for traffic along SR 99. The existing trips from properties that would be acquired are shown in Figure G1.4-7, and the existing trips that would be rerouted due to changes in the roadway network are shown in Figure G1.4-8.

The peak hour vehicle trips generated by the Preferred Alternative OMF facility, as described in Section 4.2.1.1 and shown in Table G1.4-8, were then assigned to study area roadways and intersections based on existing travel patterns and are summarized in Figure G1.4-9.

As discussed under the No-Build Alternative, traffic volumes are forecast to increase throughout the study area during both the 2042 AM and PM peak hours as a result of planned population and employment growth by the local jurisdictions. Figure G1.4-10 shows the forecast 2042 AM and PM peak hour turning movements under the Preferred Alternative.

DRAFT: For internal discussion only. Not reviewed or approved on behalf of any party.

4.2.2.3 Intersection Operations

The forecast project alternatives for the 2042 AM and PM peak hour LOS as well as delay for the study area intersections evaluated are discussed below.

Preferred Alternative 2042 AM Analysis

Under the Preferred Alternative, no intersections are forecast to operate below the applicable LOS or v/c ratio standards for the roadway or highway, as shown in Table G1.4-11. Figure G1.4-11 shows the 2042 AM peak hour operations at the Preferred Alternative study intersections.

Table G1.4-11 Preferred Alternative 2042 AM Peak Hour Traffic Operations

ID	Intersection[1]	Control Type	Agency Standard	No Build Alternative LOS [2, 3]	No Build Alternative Delay (seconds) [2, 3]	No Build Alternative V/C Ratio [2, 3]	Preferred Alternative LOS [2, 3]	Preferred Alternative Delay (seconds) [2, 3]	Preferred Alternative V/C Ratio [2, 3]

6	18th Place S/ S 341st Place	Uncontrolled	N/A	N/A	N/A	0.03	N/A	N/A	0.06
7	SR 99/ S 344th Street	Signal	WSDOT Highways of Statewide Significance (LOS D)	B	18	N/A	B	19	N/A
8	S 344th Street/ 16th Avenue S	Signal	N/A	N/A	N/A	0.39	N/A	N/A	0.38
9	S 344th Street/ 18th Place S	Uncontrolled	N/A	N/A	N/A	0.04	N/A	N/A	0.03
11	18th Place S Extension/ S 336th Street	TWSC	N/A	-	-	-	N/A	N/A	0.01
12	18th Place S/S 340th Street	TWSC	City of Federal Way (v/c 1.0)	-	-	-	N/A	N/A	0.01

Notes:

(1) Intersection 10 (SR99/Driveway), as discussed in the 2021 SEPA Draft EIS and 2023 NEPA Draft/SEPA Supplemental Draft EIS, is no longer included because the site entrance has moved to S 341st Place, east of Intersection 6 (18th Place S/S 341st Place).

(2) Synchro analyzes intersections in isolation and does not take into account downstream congestion. Actual intersection operations may have more delay based on intersection interactions and queuing propagating upstream and downstream between intersections.

(3) Intersections were analyzed using HCM 6th Edition (Transportation Research Board 2016) for signalized and unsignalized intersections, except where HCM 6th Edition limitations necessitated use of HCM 2000 methodology (Transportation Research Board 2000).

FIGURE G1.4-12

2042 Build Alternative PM Peak Hour Traffic Operations
Preferred Alternative

N

0 500 1,000 Feet

OMF South

DRAFT: For internal discussion only. Not reviewed or approved on behalf of any party.

4.2.2.4 Freight

The Preferred Alternative is not anticipated to negatively affect truck circulation or truck routes on the local street network. The mainline would not have any at-grade roadway crossings; therefore, there would not be delays for trucks. Freight would experience the same levels of delay as general-purpose traffic on roadways and at intersections throughout the study area.

4.2.2.5 Transit

Depending on the mainline alignment, up to 50 parking spaces in the Federal Way/S 320th Street Park & Ride would be removed as part of the Preferred Alternative to accommodate the elevated mainline and a relocated BPA transmission line tower. Given the size of the Federal Way/S 320th Street Park & Ride and its low utilization, it is estimated that sufficient parking would still be available to accommodate demand with a reduction of 50 parking spaces. WSDOT has indicated that the loss of these stalls would not require replacement.

4.2.2.6 Nonmotorized Facilities

Under the Preferred Alternative, nonmotorized volumes would increase similarly to the No-Build Alternative. Pedestrian and bicycle facilities would generally be developed in a manner comparable to the No-Build Alternative. The conceptual layout of the Preferred Alternative would include bicycle lanes along the extended segment of 18th Place S and extend the eastbound bicycle lanes on S 336th Street from 20th Avenue S to SR 99, maintaining the existing bicycle network in the study area. It could also affect the future alignment of the planned trails through the Federal Way/S 320th Street Park & Ride but would not necessarily preclude them. Right-of-way improvements, which may include the development of new pedestrian and/or bicycle facilities, are planned for the Preferred Alternative. These areas include S 336th Street from SR 99 to I-5 and approximately 150 feet along 21st Avenue S south of S 341st Place.

4.2.2.7 Parking

Development of the mainline for the Preferred Alternative would require the permanent removal of approximately 10 parking stalls from the east side of The Commons at Federal Way shopping mall. There would be an abundance of parking stalls remaining at The Commons at Federal Way. Nearby developments along 18th Place S, S 341st Place, and S 344th Street currently use the street parking that would be removed; however, several of these properties would be acquired as part of the project. As a result, no adverse impacts are expected.

Impacts to the Federal Way/S 320th Street Park & Ride are described in the Transit section.

4.2.2.8 Safety

Beginning south of S 324th Street, the mainline tracks connecting the Preferred Alternative to FWLE would be constructed in the I-5 right-of-way directly adjacent to the clear zone—which is the unobstructed, relatively flat area beyond the edge of the roadway to allow drivers to stop safely or regain control of a vehicle if needed. While portions of the mainline alignment would maintain clear zone standards, there may be locations where the minimum widths cannot be met. In such instances, deviations from clear zone distances require approval from WSDOT or FHWA. Failure to meet the standard width of the clear zone could result in impacts to safety conditions and an increase in collision frequencies. In areas where minimum clear zone conditions cannot be maintained, guardrails, barriers, or impact attenuators, such as water-filled jersey barriers or sand-filled barrels, would be provided to shield vehicles from roadside hazards. As a result, the mainline along I-5 is not anticipated to have any quantifiable impact to safety along I-5.

4.2.3 South 344th Street Alternative

4.2.3.1 Roadway Network and Intersection Modifications

The roadway network would be modified under the South 344th Street Alternative. The alternative would not interfere with the potential to add a southbound auxiliary lane on 16th Avenue S, as described for the No-Build Alternative.

The South 344th Street Alternative would have two access points. The first is a visitor/employee access with a guard house would be provided at the intersection of S 344th Street and 18th Place S, allowing for access to SR 99 via 16th Avenue S or S 344th Street. The current proposal is for all employees to access the site at this location. A second access would be provided at 20th Avenue S, south of S 336th Street, with direct access to the signalized intersection at S 336th Street; however, it would not be for daily employee access to the site. The design of two study intersections would be modified as part of the South 344th Street Alternative. At intersection #6 (18th Place S/S 341st Place), the south and east legs would be removed, as they would be occupied by OMF South. The resulting traffic volumes using these legs were therefore removed from the South 344th Street Alternative analysis at this intersection.

The alternative would close 20th Avenue S 300 feet south of S 336th Street and preclude the planned extension of 20th Avenue S from S 341st Place to 344th Street, described under the No-Build Alternative. 20th Avenue S would still provide access to the Christian Faith Center from the north. Drivers and nonmotorized travelers wishing to access the remaining streets in the southern part of the study area would be required to do so via 16th Avenue S or SR 99.

4.2.3.2 Traffic Volumes

To develop traffic volumes for the South 344th Street Alternative existing trips from properties that would be acquired were removed and existing trips that would be rerouted due to changes in the roadway network were rerouted to other intersections or intersection movements. Existing trips from properties that would be acquired were estimated based on existing land uses and estimated trip generation and were confirmed with existing intersection volumes. The existing trips from properties that would be acquired are shown in Figure G1.4-13, and the existing trips that would be rerouted due to changes in the roadway network are shown in Figure G1.4-14. The peak hour vehicle trips generated by the S 344th Street facility, as described in Section 4.2.1.1 and shown in Table G1.4-8, were then assigned to study area roadways and intersections based on existing travel patterns and are summarized in Figure G1.4-15.

As discussed under the No-Build Alternative, traffic volumes are forecast to increase throughout the study area during both the 2042 AM and PM peak hours as a result of planned population and employment growth by the local jurisdictions. Figure G1.4-16 show the forecast 2042 AM and PM peak hour turning movements under the South 344th Street Alternative.

4.2.3.3 Intersection Operations

The forecast project alternatives for the 2042 AM and PM peak hour LOS as well as delay for the study area intersections evaluated are discussed below. Nearby uses, such as the Christian Faith Center, generate large traffic volumes outside of the weekday AM or PM peak hours. Given the planned arrival and departure times for staff at the facility, traffic generated by the facility is not anticipated to exacerbate existing conditions associated with church events.

South 344th Street Alternative 2042 AM Analysis

As shown in Table G1.4-13, no intersections under the South 344th Street Alternative are forecast to operate below the applicable LOS or v/c ratio standards for the roadway or highway. Figure G1.4-17 shows the 2042 AM peak hour operations at the South 344th Street Alternative study intersections.

Table G1.4-13 South 344th Street Alternative 2042 AM Peak Hour Traffic Operations

ID	Intersection	Control Type	Agency Standard	No Build Alternative LOS 1, 2	No Build Alternative Delay (seconds) 1, 2	No Build Alternative V/C Ratio 1, 2	South 344th Street Alternative LOS 1, 2	South 344th Street Alternative Delay (seconds) 1, 2	South 344th Street Alternative V/C Ratio 1, 2
1	S 336th Street/ 20th Avenue S	Signal	N/A	N/A	N/A	0.52	N/A	N/A	0.52

5	16th Avenue S/ S 341st Place	TWSC	N/A	N/A	N/A	0.15	N/A	N/A	0.02
6	18th Place S/ S 341st Place	Uncontrolled	N/A	N/A	N/A	0.03	N/A	N/A	0.00
7	SR 99/ S 344th Street	Signal	WSDOT Highways of Statewide Significance (LOS D)	B	18	N/A	B	18	N/A
8	S 344th Street/ 16th Avenue S	Signal	N/A	N/A	N/A	0.39	N/A	N/A	0.36
9	S 344th Street/ 18th Place S	Uncontrolled	N/A	N/A	N/A	0.04	N/A	N/A	0.05

Notes:

(1) Synchro analyzes intersections in isolation and does not take into account downstream congestion. Actual intersection operations may have more delay based on intersection interactions and queuing propagating upstream and downstream between intersections.

(2) Intersections were analyzed using HCM 6th Edition (Transportation Research Board 2016) for signalized and unsignalized intersections, except where HCM 6th Edition limitations necessitated use of HCM 2000 methodology (Transportation Research Board 2000).

2042 Build Alternative AM Peak Hour Traffic Operations
South 344th Street Alternative

OMF South

DRAFT: For internal discussion only. Not reviewed or approved on behalf of any party.

South 344th Street Alternative 2042 PM Analysis

Similar to the Preferred Alternative, no intersections would operate below the applicable LOS or v/c ratio standards for the roadway or highway during the PM peak hour. Table G1.4-14 and Figure G1.4-18 show the 2042 PM peak hour operations at the South 344th Street Alternative study intersections.

Table G1.4-14 South 344th Street Alternative 2042 PM Peak Hour Traffic Operations

ID	Intersection	Control Type	Agency Standard	No Build Alternative LOS 1, 2	No Build Alternative Delay (seconds) 1, 2	No Build Alternative V/C Ratio 1, 2	South 344th Street Alternative LOS 1, 2	South 344th Street Alternative Delay (seconds) 1, 2	South 344th Street Alternative V/C Ratio 1, 2

FIGURE G1.4-18

2042 Build Alternative PM Peak Hour Traffic Operations
South 344th Street Alternative

OMF South

DRAFT: For internal discussion only. Not reviewed or approved on behalf of any party.

4.2.3.4 Freight

The South 344th Street Alternative is not anticipated to negatively affect truck circulation or truck routes on the local street network. The mainline would not have any at-grade roadway crossings; therefore, there would not be delays for trucks. Freight would experience the same levels of delay as general-purpose traffic on roadways and at intersections.

4.2.3.5 Transit

Depending on the mainline alignment, up to 50 parking spaces in the Federal Way/S 320th Street Park & Ride would be removed as part of the South 344th Street Alternative to accommodate the elevated mainline and a relocated BPA transmission line tower. Given the size of the Federal Way/S 320th Street Park & Ride and its low utilization, it is estimated that sufficient parking would still be available to accommodate demand with a reduction of 50 parking spaces.

4.2.3.6 Nonmotorized Facilities

Under the South 344th Street Alternative, nonmotorized volumes would increase similarly to the No-Build Alternative. Pedestrian and bicycle facilities would generally be developed in a manner comparable to the No-Build Alternative. However, the alternative would eliminate the greenway between S 336th Street and S 344th Street. The South 344th Street Alternative would also close portions of 18th Place S and S 341st Place, effectively eliminating much of the existing street grid network in the southern part of the study area. Pedestrians and cyclists could continue to travel on the existing sidewalks on S 336th Street between SR 99 and S 344th Street. Right-of-way improvements, which may include the development of new pedestrian and/or bicycle facilities, are planned for the South 344th Street Alternative. These areas include S 341st Place and S 344th Street from SR 99 to the programmed site area boundary and 18th Place S from S 340th Street to S 341st Place. In addition, Sound Transit would evaluate options for replacing the function of the greenway between S 336th Street and S 344th Street.

4.2.3.7 Parking

Development of the mainline for the South 344th Street Alternative would require the permanent removal of approximately 10 stalls from the east side of The Commons at Federal Way shopping mall and approximately 20 from the southeast portion of the Walmart property south of S 344th Street. The South 344th Street Alternative would also displace on-street parking adjacent to developments along 21st Avenue S, S 341st Place east of 18th Place S, and S 344th Street east of 18th Place S. There would be an abundance of parking stalls remaining at The Commons mall and at Walmart. Most developments that may currently use on-street parking along 18th Place S, S 341st Place, and S 344th Street would be acquired as part of the project.

The South 344th Street Alternative may displace up to five on-street parking spaces on the south side of S 344th Street, east of 18th Place S, that may be currently used to access developments that would not be acquired. However, there would be ample space remaining for on-street parking along the south side of S 344th Street and no adverse parking impacts are expected.

Impacts to the Federal Way/S 320th Street Park & Ride are described in the Transit section.

4.2.3.8 Safety

The South 344th Street Alternative mainline would have the same safety impacts as described above for the Preferred Alternative for the majority of its length, the only difference being for the mainline tail tracks.

The Enchanted Parkway alignment would turn southwest away from the I-5 right-of-way between S 344th Street and S 359th Street. It would be elevated for this entire section and cross public streets and property access points with grade-separated crossings. For the I-5 alignment, the tail tracks would remain elevated as they travel over the I-5/S 348th St interchange right-of-way. Both tail track alignments would adhere to current design standards and would not be expected to result in safety impacts.

4.2.4 Midway Landfill Alternative

4.2.4.1 Roadway Network and Intersection Modifications

Development of the Midway Landfill Alternative would not change the existing roadway network or interfere with the potential for development of planned improvements within the study area as described for the No-Build Alternative.

Three driveways to the site would be provided, including a visitor/employee access with a guard house from SR 99 at S 246th Street and employee-only access at SR 99/S 248th Street and S 252nd Street/30th Avenue S. Left-turn access into or out of the site at the S 246th Street driveway is currently prohibited by a c-curb. However, the project would modify it to allow left turns by southbound drivers. Left turns into the site at S 248th Street are permitted via a southbound left-turn pocket, but left turns out of the site are prohibited by a c-curb. These would be unsignalized access points. Access at S 252nd Street is signalized, and left turns are permitted at the intersection. The northern and southern driveways on SR 99 would be located at intersections #4 and #5, respectively. Intersection #10, the south driveway at 30th Avenue S and S 252nd Street, was not evaluated under the No-Build Alternative.

For the Midway Landfill Alternative, there are two driveways that are accessible from SR 99. Some drivers arriving or departing during the peak time period will use the parking area that is closest to the MOW and Link System-Wide Storage facilities and will enter using the southernmost driveway. Drivers who are required to enter the gate controlled area will use the driveway to the north.

4.2.4.2 Traffic Volumes

To develop traffic volumes for the Midway Landfill Alternative, existing trips from properties that would be acquired were removed. These trips were estimated based on existing land uses and estimated trip generation and were confirmed with existing intersection volumes. The peak hour vehicle trips generated by the Midway Landfill Alternative facility, as described in Section 4.2.1.1 and shown in Table G1.4-8, were assigned to study area roadways and intersections based on existing travel patterns and are summarized in Figure G1.4-19.

As discussed under the No-Build Alternative, traffic volumes are forecast to increase throughout the study area during both the 2042 AM and PM peak hours as a result of planned population and employment growth by local jurisdictions. Figure G1.4-20 shows the forecast 2042 AM and PM peak hour turning movements under the Midway Landfill Alternative.

4.2.4.3 Intersection Operations

The forecast project alternatives for the 2042 AM and PM peak hour LOS as well as delay for the study area intersections evaluated are discussed below.

Midway Landfill Alternative 2042 AM Analysis

As shown in Table G1.4-15, four intersections are forecast to operate below the LOS standards for the Midway Landfill Alternative study area during the AM peak period. The four intersections are intersection #2 (SR 99/S 244th Street), intersection #3 (SR 99/Midway Mobile Home Park Driveway), intersection #4 (SR 99/S 246th Street), and intersection #5 (SR 99/S 248th Street). Intersections #2, #3, and #5 are forecast to operate below the LOS standard under the No-Build Alternative, and the project would not add any delay at these intersections.

As stated above, LOS for signalized intersections is based on average intersection delay, while LOS for unsignalized intersections is based on the worst approach. Intersection #4 is not forecast to operate below the LOS standard for the highway under the No-Build Alternative because it is a t-intersection with right-in/right-out access for the southbound direction only. With the build alternative, the configuration would be changed to allow southbound left turns that must cross three lanes of traffic to access the site. This change in intersection configuration would result in LOS F operations. There are only 17 vehicles forecast to cross the northbound traffic for access into the Midway Landfill site, but the opposing northbound morning peak hour traffic volume of over 2,550 vehicles using three lanes of traffic is high enough that the southbound left turn delay would exceed the LOS F threshold. The remaining legs of the intersection operate within an acceptable LOS.

Vehicles turning left into the OMF South facility access point at S 246th Street would experience 84 seconds of delay. These vehicles may instead choose to continue traveling south to make a U-turn at S 252nd Street and turn right into the access point at S 246th Street.

For intersections #4 and #5 (the driveway entrances to the site), southbound queueing at the intersections is not anticipated to extend beyond the current and constructed storage lengths of the left-turn lanes. While still operating below the LOS standard for SR 99 with the project, operations at intersection #5 would improve with the project, as trips currently using the driveway would no longer do so.

Figure G1.4-21 shows the 2042 AM peak hour operations at the Midway Landfill Alternative study intersections.

Table G1.4-15 Midway Landfill Alternative 2042 AM Peak Hour Traffic Operations

ID	Intersection	Control Type	Agency Standard	No Build Alternative LOS 1, 2, 3, 4	No Build Alternative Delay (seconds) 1, 2, 3, 4	Midway Landfill Alternative LOS 1, 2, 3, 4	Midway Landfill Alternative Delay (seconds) 1, 2, 3, 4

7	SR 99/ S 260th Street	Signal	WSDOT Highways of Statewide Significance (LOS D)	D	47	D	47
8	29th Avenue S/ S 252nd Street	TWSC	City of Kent (LOS E)	A	9	A	9
9	29th Avenue S/ S 259th Street	TWSC	City of Kent (LOS E)	C	22	C	22

Notes:

(1) Synchro analyzes intersections in isolation and does not take into account downstream congestion. Actual intersection operations may have more delay based on intersection interactions and queuing propagating upstream and downstream between intersections.

(2) Cells highlighted in ***gray bold and italicized*** identify intersections that operate below the LOS standard for the roadway/highway.

(3) Intersections were analyzed using the Synchro outputs for signalized intersections and 2010 Highway Capacity Manual (Transportation Research Board 2010) outputs for unsignalized intersections.

(4) At signalized intersections utilizing HCM 6th Edition methodology (Transportation Research Board 2016), U-turn movements were added to left-turn movements to allow for analysis.

DRAFT: For internal discussion only. Not reviewed or approved on behalf of any party.

Midway Landfill Alternative 2042 PM Analysis

As shown in Table G1.4-16, Intersections #2 (SR 99/S 244th Street) and #5 (SR 99/S 248th Street) are forecast to operate below the LOS standard for the highway in the project alternatives, with forecast increases in delay of 5 seconds for both intersections. Since the increased delay is less than 10 seconds, it would not be considered an impact that would require mitigation. No other intersections under the Midway Landfill Alternative are forecast to operate below the LOS standard for the roadway or highway.

Figure G1.4-22 shows the 2042 PM peak hour operations at the Midway Landfill Alternative study intersections.

Table G1.4-16 Midway Landfill Alternative 2042 PM Peak Hour Traffic Operations

ID	Intersection	Control Type	Agency Standard	No Build Alternative LOS 1, 2, 3, 4	No Build Alternative Delay (seconds) 1, 2, 3, 4	Midway Landfill Alternative LOS 1, 2, 3, 4	Midway Landfill Alternative Delay (seconds) 1, 2, 3, 4

2042 Build Alternative PM Peak Hour Traffic Operations
Midway Landfill Alternative

OMF South

DRAFT: For internal discussion only. Not reviewed or approved on behalf of any party.

4.2.4.4 Freight

Impacts to freight would be similar to those for the No-Build Alternative. There are no at-grade light rail track profiles that would result in additional crossings or delays for trucks. Freight would experience the same levels of delay as general-purpose traffic on roadways and at intersections.

4.2.4.5 Transit

It is assumed the bus service network under the build alternatives would be the same as the No-Build Alternative. Additional bus service levels or rerouting to the facility are not anticipated for any alternatives. The existing pair of Metro RapidRide stops at SR99/S 246th Street would need to be relocated to accommodate development of the Midway Landfill Alternative.

Due to the lack of a dedicated test track, Sound Transit would continue testing LRVs on existing mainline tracks during off-peak periods and at night during non-revenue hours when the rail system is closed to passenger service. This limits the daily time available to test and commission vehicles because those same tracks are used for passenger service and movement of rail vehicles during maintenance and inspection periods. The lack of a dedicated test track would increase the amount of time required to commission new LRVs and could therefore result in insufficient vehicle quantities available to meet system expansion requirements under Sound Transit 3. In addition, the lack of a dedicated test track would slow the rehabilitation and replacement of the existing fleet of LRVs. As a result, light rail operations would be less efficient than they would otherwise be, and Sound Transit may not be able to meet expected ridership demand.

4.2.4.6 Nonmotorized Facilities

Nonmotorized volumes would increase similarly to the No-Build Alternative. Pedestrian and bicycle facilities would generally be developed in a manner comparable to the No-Build Alternative. However, facilities that were planned to cross through the site could not be developed. These include the unfunded north-south improvements connecting S 244th Street to S 252nd Street facilities that were planned to cross through the conceptual layout areas, as described in the No-Build Alternative, within the Midway Landfill Alternative study area.

Right-of-way improvements, which may include the development of new pedestrian and/or bicycle facilities are planned for each alternative. These areas include SR 99 between approximately S 244th Street and S 248th Street.

Impacts on nonmotorized facilities included a qualitative assessment of the potential for the build alternatives to alter operations of pedestrian and bicycle facilities in the study area. There are limited nonmotorized facilities in the Midway Landfill Alternative study area, none of which are impacted by the project. The project also would not impact circulation through or connections to existing nonmotorized facilities in the study area, as the Midway Landfill currently serves as a barrier. Pedestrians and cyclists could continue to use the existing facilities on SR 99. The planned nonmotorized improvements within the project footprint, including the north-south path and internal pedestrian and bike paths, could not be developed.

Should future nonmotorized facilities be developed north of the Midway Landfill Alternative, a north-south shared-use path could be developed by others to provide a connection to the area south of the project site. S 244th Street could be developed as a complete street along a part of its length. The project would not impact the potential to develop a bicycle-pedestrian bridge across I-5 at S 240th Street.

4.2.4.7 Parking

Impacts to parking are described under Long-Term Impacts Common to all Build Alternatives.

4.2.4.8 Safety

Impacts to safety would be similar to those for the No-Build Alternative.

4.3 Construction Impacts

All the build alternatives would require some preparatory demolition activities and earthwork that would generate truck trips. Material delivery and general construction vehicle activity would also contribute to construction-related traffic. As most of this activity would occur during import and export of material to and from the site during site preparation, the estimated volumes of truck traffic presented in the following sections focus on that early period of peak construction traffic to present the worst-case scenario.

Impacts associated with construction truck activities were calculated by assigning a passenger car equivalent (PCE) to each truck trip. The PCE factor converts the number of trucks to an estimated number of passenger cars. The HCM recommends a range of PCE factors for trucks from 1.1 to 2.5.

For the purposes of this analysis, it was assumed that all export and import material would be transported to and from the site in dump trucks with trailers that have a capacity of 20 cubic yards. Given their size and slower operating speeds, trucks were assigned a PCE value of 2.5, meaning one construction truck is equivalent to two-and-a-half passenger cars. Using a factor of 2.5 for this analysis provides a reasonable impact estimate for the size and weight of the trucks and allows for an equal comparison across alternatives. The PCE factor was calculated for both inbound and outbound trips.

4.3.1 Preferred Alternative

Only one development scenario is assumed for the Preferred Alternative OMF site. It would require demolition of existing structures, export of building debris and excavated material, and import of in-place fill material. This development scenario assumes reuse of 80 percent of on-site material, resulting in lower truck volumes than if all excavated material is exported and all fill material is imported.[4] The construction impact area for the Preferred Alternative would extend from the Federal Way Downtown Station and include portions of the S 320th Street Park & Ride and the Belmor Park Golf and Country Club as well as other residential properties near I-5. The construction impact area for the site associated is shown in Figure G1.4-23.

---

[4] Does not include excavation associated with columns for aerial mainline tracks, repaving roadways (mostly at grade), or other construction-related quantities. Import volumes assume importation of 60,000 cubic yards of fill material.

OMF South

4.3.1.1 Estimation of Construction Truck Traffic

Site preparation work is expected to last approximately 1 year and 5 months, assuming 12-hour workdays, 6 days per week. All export and import material would be transported to and from the site in dump trucks with trailers with an assumed capacity of 20 cubic yards. Export activity would result in approximately 24 truck trips per day and import activity would result in approximately 21 truck trips per day. Table G1.4-17 summarizes the quantity of export and import material estimated for development of the Preferred Alternative, the associated truck trips, and the estimated durations of work.

Table G1.4-17 Truck Activity Associated with Site Preparation for the Preferred Alternative

Export Material (ton)	Export Total Truck Trips per Day	Export Total Project Truck Trips	Import In Place (cubic yards)	Import Total Truck Trips per Day	Import Total Project Truck Trips	Site Preparation Duration
205,000	24	10,250	185,000	21	9,250	1 yr, 5 mos

4.3.1.2 Potential Construction Access and Truck Haul Routes

Construction access at the Preferred Alternative would be provided at three locations: S 336th Street at 20th Avenue S, SR 99 at the existing driveway to the Christian Faith Center, and S 341st Place at 20th Avenue S. Construction access for the potential mainline track construction from the Federal Way Downtown Station to S 344th Street would occur at S 324th Street, S 330th Street, and S 336th Street. Trucks would access northbound and southbound I-5 at the S 320th Street and S 348th Street interchanges via SR 99. Construction access and truck routes are shown in Figure G1.4-24. To minimize impacts to traffic circulation during construction and meet Federal Way requirements, Sound Transit would extend 18th Place S or construct a temporary public roadway through the construction site prior to closure of 20th Avenue S.

4.3.1.3 Changes to Traffic Volumes

OMF South Site Construction

Trucks would traverse the haul routes during the entirety of the 12-hour daily construction period, to and from the site during AM and PM peak periods. As described in Section 4.3.1.1, this equates to approximately 24 round trips per day associated with export and 21 round trips per day associated with import. With 45 truck trips during the daily construction period, the average number of truck trips per hour would be 3 to 4.

Each truck round trip includes an outbound and inbound segment, resulting in a total of 113 PCE daily trips in the study area associated with export activity (45 truck trips x 2.5 PCE).

FIGURE G1.4-24
Construction Access and Truck Routes
Preferred Alternative

OMF South

To estimate traffic operation impacts, the truck trips are assumed to be distributed evenly throughout the daily construction period and are based on the ability of the yard and receiving facility to process the trucks.[5] A similar 2.5 PCE factor is applied to the truck volume to estimate the number of new trips that would need to be accommodated along the truck routes. Table G1.4-18 summarizes the number of peak hour trucks and associated PCEs for each construction scenario.

Table G1.4-18 Hourly Truck Activity Associated with Preferred Alternative Development Approaches

Hourly Trucks Export	Hourly Trucks Import	Hourly Trucks Total	PCE
2	1–2	3–4	8-10

The PCEs shown in the table would be distributed with half exiting the site and half entering the site during the peak hour.

The haul routes would be located on state facilities, including SR 99, SR 18 (S 348th Street), and I-5, as well as several collector and arterial streets. Because the construction staging, origin of the import material, and destination for export material are unknown at this time, the volumes forecast on each roadway segment represent the highest possible volumes for all daily construction activity. A single potential roadway identified as a haul route could be used for all daily truck trips or the total daily volumes could be distributed among multiple roadways. Trucks would travel in a single direction on roadways along the haul routes. The estimated daily truck PCE trips associated with site preparation would represent up to 22.6 percent of existing single-direction traffic on collector and arterial roadways. Estimated daily truck PCE trips would represent up to 1.9 percent of the existing single-direction AADT for all state facilities, with the highest percentages at on- and off-ramps. Table G1.4-19 summarizes AADT on streets that are part of the haul routes as well as the estimated truck trips as a percentage of AADT. Figure G1.4-25 displays the location of AADT counts.

Table G1.4-19 Estimated Hourly Truck Activity at the Preferred Alternative Compared with Existing AADT

Intersection/Roadway Segment	Existing AADT (Both Directions)[1]	Existing AADT (Single Direction)[1]	Daily Truck Trips as a Percentage of Single Direction AADT
S 320th Street: SR 99 to I-5	>35,000	>17,500	<0.6%

FIGURE G1.4-25
Existing Annual Average Daily Traffic Along Truck Haul Routes
Preferred Alternative

OMF South

DRAFT: For internal discussion only. Not reviewed or approved on behalf of any party.

Mainline Construction

Mainline construction, including the mainline tail tracks, is expected to take 15 months. Construction of the mainline would require temporary full and/or partial closures to streets that travel beneath the mainline.

As with site construction, all export and import material would be transported to and from the site in dump trucks with trailers with an assumed capacity of 20 cubic yards. Peak truck trips during mainline construction are estimated to be up to 10 trucks per hour for concrete delivery, or up to 120 trips per day (300 PCE), assuming 12 hours per day of active construction, some of which may occur at night. A similar level of truck activity is expected for earthwork activities, but this would be focused on trucks hauling material during excavation and would not overlap with concrete delivery trucks. Haul routes for mainline construction are anticipated to be the same as described above for OMF site construction.

Truck trips on roadways would be expected to increase proportionately above those associated with site construction should mainline and site construction occur concurrently. Streets with the lowest existing AADT, such as S 336th Street and S 344th Street, would experience the highest relative growth in traffic compared to existing volumes.

4.3.1.4 Impacts to Property Access

Impacts to property access for sites in the vicinity of the Preferred Alternative would be minimal. Trucks entering or exiting the site are not expected to block driveways along the haul routes. Access to properties fronting SR 99, S 336th Street, S 340th Street, S 341st Place, 18th Place S, and 21st Avenue S would be impacted during construction of right-of-way improvements in these areas. If driveway closures are required, access to these properties would be maintained to the extent practical. If access to a business could not be maintained during construction, the specific construction activity would be reviewed to determine whether it could occur during non-business hours.

4.3.1.5 Impacts to Transit

During construction of the Preferred Alternative, transit service on S 324th Street, S 336th Street, and 23rd Avenue S would likely be impacted. Buses may need to be rerouted and bus stops may need to be temporarily relocated in response to construction-related road closures. Bus service may also be slower and less reliable in construction areas. Bus service into the Federal Way/S 320th Park & Ride may need to be rerouted to avoid construction areas. Of the 877 parking spaces at the Federal Way/S 320th Street Park & Ride, about 650 spaces would be temporarily closed during mainline track construction. In the first quarter of 2023, utilization of the Park & Ride was at 1.3 percent. While this lot has not been used at capacity in recent years, utilization could change with the opening of FWLE, which has a forecasted in-service date of 2026.

4.3.1.6 Impacts to Nonmotorized Facilities

Because the construction area includes all of the S 336th Street programmed site area, the impacts to pedestrian and bicycle facilities during construction and upon completion of the facility would be similar. The current north-south greenway would be closed, and bicycle lanes would be reopened with construction of the extended 18th Place S roadway. Pedestrian and bicycle facilities on S 324th Street, S 330th Street, S 336th Street, S 340th Street, S 341st Place, 18th Place S, 21st Avenue S, and 23rd Avenue S would be impacted during construction of right-of-way improvements in these areas.

4.3.1.7 Impacts to Parking

Most construction activity, including staging, is expected to occur within the boundaries of the Preferred Alternative. Construction of the mainline would require the temporary closure of parking stalls at The Commons at Federal Way shopping mall. On-street parking along streets where roadway frontage improvements are planned would be prohibited within the active construction area. However, these impacts would be temporary and transitory as construction activity progressed.

4.3.2 South 344th Street Alternative

Only one development scenario is assumed for the South 344th Street Alternative OMF site. It would require demolition of existing structures, export of building debris and excavated material, and import of in-place fill material.[6] This development scenario assumes reuse of 80 percent of on-site material, resulting in lower truck volumes than if all excavated material is exported and all fill material is imported. The construction impact area for the South 344th Street Alternative would extend from the Federal Way Downtown Station and include portions of the Federal Way/S 320th Street Park & Ride and Belmor as well as other properties near I-5. It would include the entirety of the permanent impact area. The construction impact area for the site is shown in Figure G1.4-26.

4.3.2.1 Estimation of Construction Truck Traffic

Site preparation work is expected to last approximately 1 year and 6 months, assuming 12-hour workdays, 6 days per week. All export and import material would be transported to and from the site in dump trucks with trailers with an assumed capacity of 20 cubic yards. Export activity would result in approximately 67 truck trips per day, and import activity would result in approximately 10 truck trips per day. Table G1.4-20 summarizes the quantity of export and import material estimated for development of the South 344th Street Alternative, the associated truck trips, and the estimated durations of work.

---

[6] Does not include excavation associated with columns for aerial mainline tracks, repaving roadways (mostly at grade), or other construction-related quantities. Import volumes assume importation of 60,000 cubic yards of fill material.

South 344th Street Alternative

OMF South

Table G1.4-20 Truck Activity Associated with Site Preparation for South 344th Street Alternative Development Approaches

Export Material (ton)	Export Total Truck Trips per Day	Export Total Project Truck Trips	Import In Place (cubic yards)	Import Total Truck Trips per Day	Import Total Project Truck Trips	Site Preparation Duration
420,000	67	21,000	60,000	10	3,000	1 yr, 6 mos

4.3.2.2 Potential Construction Access and Truck Haul Routes

Construction access at the South 344th Street Alternative would be provided at two locations: S 336th Street at 20th Avenue S and via direct access from S 344th Street. Construction access for the potential lead track construction from the Federal Way Downtown Station to S 344th Street would occur at S 324th Street, S 330th Street, and S 336th Street. Trucks would access northbound and southbound I-5 at the S 320th Street and S 348th Street interchanges via SR 99. Construction access and truck routes are shown in Figure G1.4-27.

4.3.2.3 Changes to Traffic Volumes

OMF South Site Construction

Trucks would traverse the haul routes during the entirety of the 12-hour daily construction period, to and from the site during AM and PM peak periods. As described in Section 8.1.1, this equates to approximately 67 round trips per day associated with export and 10 round trips per day associated with import. With 77 truck trips during the daily construction period, the average number of truck trips per hour would be 7.

Each truck round trip includes an outbound and inbound segment, resulting in a total of 193 PCE daily trips in the study area associated with export activity (77 truck trips x 2.5 PCE).

To estimate traffic operation impacts, the truck trips are assumed to be distributed evenly throughout the daily construction period and are based on the ability of the yard and receiving facility to process the trucks.[7] A similar 2.5 PCE factor is applied to the truck volume to estimate the number of new trips that would need to be accommodated along the truck routes. Table G1.4-21 summarizes the number of peak hour trucks and associated PCEs for each construction scenario.

Table G1.4-21 Hourly Truck Activity Associated with South 344th Street Alternative Development Approaches

Hourly Trucks Export	Hourly Trucks Import	Hourly Trucks Total	PCE
6	1	7	18

The PCEs shown in the table would be distributed with half exiting the site and half entering the site during the peak hour.

Construction Access and Truck Routes
South 344th Street Alternative

OMF South

The haul routes would be located on state facilities, including SR 99, SR 18 (S 348th Street), and I-5, as well as several collector and arterial streets. Because the construction staging, origin of the import material, and destination for export material are unknown at this time, the volumes forecast on each roadway segment represent the highest possible volumes for all daily construction activity. A single potential roadway identified as a haul route could be used for all daily truck trips or the total daily volumes could be distributed among multiple roadways. The estimated daily truck PCE trips associated with site preparation could represent up to 38.6 percent of existing traffic on collector and arterial roadways. Daily truck PCE trips could represent as much as 3.2 percent of the existing single day AADT for all state facilities, with the highest percentages at on- and off-ramps. Table G1.4-22 summarizes AADT on streets that are part of the haul routes as well as the estimated truck trips as a percentage of AADT. Figure G1.4-28 displays the location of AADT counts.

Table G1.4-22 Estimated Hourly Truck Activity at the South 344th Street Alternative Compared with Existing AADT

FIGURE G1.4-28

Existing Annual Average Daily Traffic Along Truck Haul Routes
South 344th Street Alternative

OMF South

Mainline Construction

Mainline construction, including the mainline tail tracks, is expected to take 15 months. Construction of the mainline would require temporary full and/or partial closures to streets that travel beneath the mainline. As with site construction, all export and import material would be transported to and from the site in dump trucks with trailers with an assumed capacity of 20 cubic yards. Peak truck trips during mainline construction are estimated to be up to 10 trucks per hour for concrete delivery, or up to 120 trips per day (300 PCE), assuming 12 hours per day of active construction, some of which may occur at night. A similar level of truck activity is expected for earthwork activities, but this would be focused on trucks hauling material during excavation and would not overlap with concrete delivery trucks. Haul routes for mainline construction are anticipated to be the same as described above for OMF site construction.

Truck trips on roadways would be expected to increase proportionately above those associated with site construction should mainline and site construction occur concurrently. Streets with the lowest existing AADT, such as S 336th Street and S 344th Street, would experience the highest relative growth in traffic compared to existing volumes.

4.3.2.4 Impacts to Property Access

Impacts to property access for sites in the vicinity of the South 344th Street Alternative would be minimal. Trucks entering or exiting the site are not expected to block driveways along the haul routes. Access to properties fronting S 341st Place, S 344th Street, and 18th Place S would be impacted during construction of right-of-way improvements in these areas. If driveway closures are required, access to these properties would be maintained to the extent practical. If access to a business could not be maintained during construction, the specific construction activity would be reviewed to determine whether it could occur during non-business hours.

4.3.2.5 Impacts to Transit

During construction of the South 344th Street Alternative, transit service on S 324th Street, S 336th Street, and 23rd Avenue S would likely be impacted. Buses may need to be rerouted and bus stops may need to be temporarily relocated in response to construction-related road closures. Bus service may also be slower and less reliable in construction areas. Bus service into the Federal Way/S 320th Park & Ride may need to be rerouted to avoid construction areas. Of the 877 parking spaces, about 650 spaces within the Federal Way/S 320th Street Park & Ride would be temporarily closed during mainline track construction. In the first quarter of 2023, utilization of the Park & Ride was at 1.3 percent. While this lot has not been used at capacity in recent years, utilization could change with the opening of FWLE, which has a forecasted in-service date of 2026.

4.3.2.6 Impacts to Nonmotorized Facilities

Because the construction area includes all of the South 344th Street Alternative, the impacts to pedestrian and bicycle facilities during construction and upon completion of the facility would be the same. The greenway between S 336th Street and S 344th Street would be closed. The South 344th Street Alternative would also close portions of 18th Place S and S 341st Place, effectively eliminating much of the existing street grid network in the southern part of the study area. Pedestrian facilities on S 324th Street, S 330th Street, S 341st Place, S 344th Street, 18th Place S, and 23rd Avenue S would be impacted during construction of right-of-way improvements in these areas.

4.3.2.7 Impacts to Parking

Most construction activity, including staging, is expected to occur within the boundaries of the South 344th Street Alternative. Construction of the mainline would require the temporary closure of parking stalls at The Commons at Federal Way shopping mall and Walmart properties. On-street parking along streets where roadway frontage improvements are planned would be prohibited within the active construction area. However, these impacts would be temporary and transitory as construction activity progressed.

4.3.3 Midway Landfill Alternative

The Midway Landfill Alternative has three subsurface construction design options to address the risk of settlement and the presence of contaminated material. Each of these subsurface construction design options would have different construction and transportation impacts. The options generally have the same horizontal layout and above-grade features but vary in subgrade and foundation approaches. The options include Platform, Hybrid, and Full Excavation and are discussed briefly below. The construction impact area for the site associated with all subsurface construction design options is shown in Figure G1.4-29.

Platform

Under this subsurface construction design option, OMF South would be built on a 6-inch thick, cast-in-place concrete slab supported on drilled shafts. The drilled shafts would be 10 feet in diameter, distributed on a 35-foot by 70-foot grid under the buildings, track, and drainage vault area. Average shaft lengths would range from 130 feet to 180 feet deep below finished grade. No new fill material is anticipated to be imported for this subsurface construction design option.

Hybrid

Under this subsurface construction design option, the entire landfill cap system would be removed and replaced. Approximately 4.3 million cubic yards of loose landfill material would be excavated, and a ground improvement process called deep dynamic compaction would be used to prepare the site for construction. A concrete slab like the one described for the Platform subsurface construction design option would be built beneath buildings sensitive to settlement, to provide additional support where needed. Tracks, parking, and roads would be built on a slab without underlying drilled shafts. Approximately 1.2 million cubic yards of loose material would need to be brought to the site.

Full Excavation

This subsurface construction design option was designed to completely excavate the landfill, which would produce roughly 4.9 million cubic yards of loose material, 3.0 million cubic yards of which would be hauled off site. Roughly 1.6 million cubic yards of competent soil would be imported. The OMF South site would be constructed on the new, imported soil.

Construction Impact Area
Midway Landfill Alternative

OMF South

DRAFT: For internal discussion only. Not reviewed or approved on behalf of any party.

4.3.3.1 Estimation of Construction Truck Traffic

Depending on which subsurface construction design option is chosen, site preparation at the Midway Landfill Alternative could take up to approximately 5 years and 7 months, assuming 12-hour workdays, 6 days per week. For all the subsurface construction design options, excavated material for export off site is assumed to be loaded into 20-foot intermodal containers on waiting trucks. The intermodal containers would be loaded only to a maximum capacity of 30 tons due to roadway load restrictions. The containers would be transported off site for direct load onto rail at an intermodal facility, from which they would then travel to a Subtitle D landfill. The site is assumed to be able to accommodate four active truck-loading locations with an on-site load time of 10 minutes each. Each load station at the Midway Landfill would be able to accommodate up to 10 trucks, for a total of up to 40 trucks operating throughout the day, including AM and PM peak periods.

The estimated total round-trip time for a truck exporting material from the site would be 100 minutes. Based on a 12-hour workday, each truck could make seven trips per day. At 40 operating trucks, there would be as many as 280 truck trips per day associated with excavation. This is an approximate value that does not account for irregularity at the beginning and end of the day.

Imported material would need to be delivered separately from the export operation. Trucks would need to be dump trucks with trailers with an assumed capacity of 20 cubic yards, and the export trucks with their intermodal containers would not be compatible with the backfill operation. It is estimated that up to 284 additional truck trips (Hybrid) would be needed to provide import material.

The estimated total round-trip time for import trucks is 100 minutes, consistent with export trucks. This assumption is not based on a particular location. When on site, trucks would dump either in the fill area or at a stockpile location. The demand for import material is expected to be less than the export effort for each subsurface construction design option. The total number of import trucks is assumed to be equally distributed throughout the export duration.

Concrete import for shafts and slabs is assumed to arrive in 9 cubic yard truckloads. The import is assumed to be equally distributed throughout the landfill preparation. Concrete will be locally sourced from an unknown location and is expected to be imported following the same site access requirements as other import and export operations.

Table G1.4-23 summarizes the quantity of export and import material estimated for each subsurface construction design option, the associated truck trips, and the estimated durations of work. Depending on the subsurface construction design option chosen, there could be up to 564 round trip truck trips per day during site preparation work. The estimates of truck traffic are conservative because at this time it is unknown how much excavated material could be used as fill material elsewhere on the same site.

Table G1.4-23 Truck Activity Associated with Site Preparation for Midway Landfill Alternative Subsurface Construction Design Options

Subsurface Construction Design Options	Export Material (ton)	Total Export Truck Trips per Day	Soil Import (cubic yards)	Concrete Import	Total Import Truck Trips per Day	Total Truck Trips per Day	Total Site Preparation Duration (years, months)
Platform	678,000	20	0	531,000	51	71	4 y, 1 m
Hybrid	2,592,000	280	1,240,000	165,000	284	564	5 y, 7 m
Full Excavation	2,956,500	280	1,610,000	0	274	554	4 y, 4 m

4.3.3.2 Potential construction access and truck haul routes

Construction access to the site would be limited to a single driveway at SR 99 and S 246th Street. Outbound trucks exiting the site to transport excavated materials would travel north on SR 99 and access I-5 via Kent-Des Moines Road (SR 516) to reach the intermodal terminal. Inbound trucks would travel south on I-5, exiting at S 272nd Street. They would travel westbound on S 272nd Street to SR 99, where they would turn north and travel to the site. Access to the site for outbound and inbound trucks would be via right turns into and out of the site. No left turns into or out of the site are assumed. Trucks importing material would follow the same routes, although the assumed origin for import material is unknown.

Construction access and truck routes are shown in Figure G1.4-30.

Due to their weight, large trucks would require additional time to accelerate to general-purpose traffic speeds on SR 99 when leaving the site and additional time to decelerate when entering the site. The substantial number of truck trips required for the Hybrid and Full Excavation subsurface construction design options would result in a greater potential to increase traffic congestion along SR 99 than the Platform subsurface construction design option or the Preferred or South 344th Street alternatives.

4.3.3.3 Changes to Traffic Volumes

Trucks would traverse the haul routes during the entirety of the 12-hour daily construction period, including both directions during AM and PM peak periods. As described in Section 4.3.1.1, the maximum number of export trucks operating at the site is 40, each performing 7 round trips per day, for a total of 280 daily truck trips. With 280 truck trips during the daily construction period, the average number of truck trips per hour would be 23 to 24. The maximum forecast daily truck trip volume associated with soil and/or concrete import is estimated at 284 trips per day, which equates to 24 additional trucks operating at the site each day.

Each truck round trip includes an outbound and inbound segment, resulting in a total of 700 PCE daily trips in the study area associated with export activity (280 truck trips x 2.5 PCE). Import activity would result in up to 710 PCE daily trips in the study area (284 truck trips x 2.5 PCE).

FIGURE G1.4-30

Construction Access and Truck Routes
Midway Landfill Alternative

OMF South

DRAFT: For internal discussion only. Not reviewed or approved on behalf of any party.

To estimate traffic impacts, the truck trips are assumed to be distributed evenly throughout the daily site preparation period and are based on the ability of the yard and receiving facility to process the trucks.[8] This information was developed to inform the Conceptual Landfill Site Reuse Plan, part of a preliminary engineering effort for the site (Sound Transit 2020b). A similar 2.5 PCE factor is applied to the truck volume to estimate the number of new trips that would need to be accommodated along the truck routes. Table G1.4-24 summarizes the number of peak hour trucks and associated PCEs for each construction scenario.

Table G1.4-24 Hourly Truck Activity Associated with Midway Landfill Alternative Subsurface Construction Design Options

Subsurface Construction Design Option	Hourly Trucks Export	Hourly Trucks Import	Hourly Trucks Total	Hourly PCE
Platform	2	5	7	18
Hybrid	24	24	48	120
Full Excavation	24	24	48	120

Source: Sound Transit (2020b).

The PCEs shown in the table would be distributed with half exiting the site and half entering the site during the peak hour. The Hybrid and Full Excavation subsurface construction design option would have the same daily truck traffic, with 120 PCE per hour.

The haul routes would be located predominantly on state facilities, including SR 99, SR 516, and I-5, as well as S 272nd Street. Trucks would travel in a single direction on roadways along the haul routes. Because the location of the intermodal facility and the origin of the import material are unknown at this time, the volumes forecast on the I-5 on- and off-ramps represent the maximum forecast for a given direction and would not be present on all ramps. For example, if the intermodal facility and the origin of the import material are located to the north of the Midway Landfill Alternative, there would be no truck activity on the southbound I-5 on-ramp from SR 516 or the S 272nd Street off-ramp from northbound I-5. The estimated daily PCE truck trips associated with site preparation for the Platform option would represent no more than 2.9 percent of the existing single direction annual average daily traffic (AADT) for all roadway segments. For the Hybrid and Full Excavation options, estimated daily PCE truck trips on all segments of the haul route, except I-5 and the ramps, would range from 7.7 percent to 12.8 percent of existing single-direction AADT. Daily PCE truck trips would range from 11.5 percent to 22.7 percent of single-direction AADT on I-5 on- and off-ramps. Table G1.4-25 summarizes AADT on streets that are part of the Midway Landfill Alternative haul routes as well as the estimated truck trips as a percentage of AADT. Figure G1.4-31 displays the location of AADT counts.

---

[8] Irregularity or bunching at the beginning and end of the day is possible.

Table G1.4-25 Estimated Daily Truck Activity for the Midway Landfill Alternative Compared with Existing AADT

Intersection/Roadway Segment	Existing AADT (Both Directions)[1]	Existing AADT (Single Direction)[1]	Daily Truck Trips as a Percentage of Single Direction AADT Platform Option	Daily Truck Trips as a Percentage of Single Direction AADT Hybrid Option	Daily Truck Trips as a Percentage of Single Direction AADT Full Excavation Option

SR 99: South of 252nd Street	29,000	14,500	1.2%	9.7%	9.6%

Sources: WSDOT Traffic GeoPortal (2020a); City of Kent Average Daily Traffic Volume (2009).

Note:

(1) WSDOT and the city of Kent report annual average daily trips (AADT) for roadways. Where roadways are bi-directional, the AADT reported reflects both directions. Single-direction volumes were determined by dividing bi-directional volumes in two.

4.3.3.4 Impacts to Property Access

Impacts to property access for sites in the vicinity of the Midway Landfill Alternative would be minimal. Trucks entering or exiting the site are not expected to block driveways along the haul routes. Properties with access to SR 99 between approximately S 244th Street and S 248th Street and with access to S 252nd Street from 29th Avenue S to the eastern terminus of the street would experience intermittent impacts to access associated with right-of-way improvements constructed as part of the project. Access to properties fronting SR 99 and S 252nd Street would be impacted during construction of right-of-way improvements in these areas.

FIGURE G1.4-31
Existing Annual Average Daily Traffic Along Truck Haul Routes
Midway Landfill Alternative

OMF South

DRAFT: For internal discussion only. Not reviewed or approved on behalf of any party.

4.3.3.5 Impacts to Transit

During construction of the Midway Landfill Alternative, transit service on SR 99 would likely be impacted. Buses may need to be rerouted off SR 99, and bus stops at S 246th Street and 252nd Street, served by King County Metro A Line, may need to be temporarily relocated in response to construction related road closures. Bus service may also be slower and less reliable in construction areas. Because FWLE would be operational by the time construction would begin, there would be some disruption of light rail service in order to connect the lead tracks of the OMF.

4.3.3.6 Impacts to Nonmotorized Facilities

Because all construction activity, including staging, is expected to occur within the boundaries of the Midway Landfill Alternative study area, minimal impacts to pedestrian and bicycle facilities are anticipated. The only existing pedestrian or bicycle facilities in the Midway Landfill Alternative study area are on SR 99 along the project frontage. This frontage is expected to remain open during construction. Pedestrians or cyclists may experience additional delay waiting for trucks to enter or exit the property. Pedestrians and cyclists traveling on SR 99 between approximately S 244th Street and S 248th Street and with access to S 252nd Street from 29th Avenue S to the eastern terminus of the street would experience intermittent impacts access associated with right-of-way improvements constructed as part of the project.

4.3.3.7 Impacts to Parking

Most construction activity, including staging, is expected to occur within the boundaries of the Midway Landfill Alternative. On-street parking along streets where roadway frontage improvements are planned would be prohibited within the active construction area. However, these impacts would be temporary and transitory as construction activity progressed.

4.4 Avoidance and Minimization of Impacts

For all build alternatives, a construction transportation management plan addressing site access, traffic control, hauling routes, impacts to transit, construction employee parking, impacts to local businesses, and pedestrian and bicycle control in the area would be prepared per city of Kent or city of Federal Way requirements and in coordination with WSDOT, as applicable. If driveway closures are required, access to these properties would be maintained to the extent practical. If access to a business could not be maintained during construction, the specific construction activity would be reviewed to determine whether it could occur during non-business hours or whether the parking and users of this access could be accommodated at an alternative location. Any properties temporarily impacted during construction would be restored as closely as possible to their previous condition.

Other avoidance and minimization measures that would be determined during the final design and permitting process could include the following:

- Install advance warning signs and highly visible construction barriers and use flaggers where needed.
- Clearly sign and provide reasonable detour routes when cross streets are closed.
- Use lighted or reflective signage to direct drivers to truck-haul routes to ensure visibility during nighttime work hours. Use special lighting for work zones and travel lanes, where required.
- Use tools such as print, radio, posted signs, websites, and email to communicate information regarding street closures, hours of construction, business access, and parking impacts.

- Coordinate with transit providers to post advance notice signs prior to construction when bus stops need to be temporarily relocated or closed.
- Post advance notice signs prior to construction in areas where construction activities would affect access to surrounding businesses.
- Schedule traffic lane closures and high volumes of construction truck traffic during off-peak hours to minimize delays, where practical.
- Cover potholes and open trenches, where possible, and use barriers to protect drivers from open trenches.

For the Preferred or South 344th Street alternatives, in locations where the mainline tracks do not meet clear zone standards and the tracks cannot be relocated, Sound Transit would work with WSDOT and FHWA to meet roadway standards by taking certain measures, such as regrading to reestablish a clear zone or installing guardrails, barriers, or impact attenuators. These measures would not adversely affect transportation safety in the study area.

4.5 Indirect Impacts

Indirect impacts are reasonably foreseeable impacts that could occur as a result of an action at some future time and in areas beyond the action's direct impacts. As an example, indirect impacts often relate to additional changes in land use that could occur beyond those changes immediately caused by a development's construction and operation, which could result in a change to overall traffic patterns. The OMF South alternatives are not expected to cause future land use changes beyond their respective sites, which could otherwise result in indirect impacts to transportation.

Development of OMF South would provide Sound Transit with capacity to receive, test, commission, store, maintain, and deploy the fleet of light rail vehicles to support the Sound Transit 3 expanded Link light rail system. This capacity would provide for more efficient operations of the existing system and allow Sound Transit to accommodate the planned future expansions of the Link light rail system to meet the expected ridership demand. Expansion of the Link light rail system would have positive indirect impacts to transportation by providing an alternative to privately owned vehicles, which could reduce the amount of vehicle miles travelled.

4.6 Cumulative Impacts

The transportation access analysis presented in the previous sections reflects conditions with assumed growth between existing conditions and the design year (2042). The traffic growth assumptions also reflect changes in traffic volumes that are projected in the traffic forecasts prepared for FWLE and TDLE. As a result, the traffic analyses reflect the cumulative impacts of these Link extensions and other planned and foreseen developments as well as associated increases in traffic within the study areas for each build alternative.

FWLE is under construction and has a forecasted in-service date of 2026. Design and construction for OMF South is planned from 2024 to 2029 or 2037, depending on the alternative. Should OMF South be located at the Midway Landfill Alternative, the FWLE construction period may overlap the planned construction period for OMF South. Both projects could potentially use the same construction staging areas and truck haul routes, including an area just to the north of the landfill and the future mainline area adjacent to I-5. There is also a potential for construction period overlap with TDLE, which is further to the south.

Federal Way's City Center Access project would construct a new I-5 interchange at S 324th Street and improvements to the existing I-5/S 320th Street interchange. This project is planned to be constructed as soon as 2027, but at this point in time, it does not have construction funding. If constructed, the project would remove a portion of parking spaces in the Federal Way/S 320th Street Park & Ride. This would be in addition to the 50 parking spaces that would be removed as part of the OMF South Preferred Alternative. Because it has not completed environmental review and is not currently fully funded, the change in traffic patterns due to the construction of the City Center Access project were not reflected in the 2042 traffic analyses for OMF South.

In addition to the parking spaces removed by OMF South, further loss of parking spaces at The Commons at Federal Way shopping mall (due to FWLE) and at Walmart (due to TDLE) are not expected to affect access to those properties due to the abundance of off-street parking within and adjacent to those properties. Any future development in those areas would need to comply with Federal Way parking requirements.

4.7 Long-Term Mitigation Measures

OMF South is not anticipated to result in long-term operational impacts to freight, transit, nonmotorized transportation, parking, or safety. Therefore, no mitigation is proposed for those transportation elements. Construction impact mitigation measures are discussed below.

Depending on the subsurface construction design option, construction of the Midway Landfill Alternative could require ingress and egress by a substantially greater number of large trucks than for the Preferred or South 344th Street alternatives. To avoid potential traffic impacts on SR 99 from the number additional trucks, short acceleration and deceleration lanes could be added to the construction entrance to the landfill site to allow outbound trucks to get up to speed and allow inbound trucks to slow down outside of the general-purpose lanes. Additional strategies to reduce impacts to local traffic during construction could include limiting truck activity during the peak traffic hours, which could extend the construction duration, or providing a direct connection to the I-5 corridor from the construction site. Such a connection would require approval by WSDOT and FHWA. If the Midway Landfill Alternative is selected, these mitigation measures would be confirmed during final design and permitting in coordination with Federal Way, WSDOT, and, if needed, FHWA.

Prior to closing a portion of the Federal Way/S 320th Street Park & Ride for construction, Sound Transit would work with King County Metro and WSDOT to determine its utilization rates and that of the nearby Federal Way Downtown Station. If the lots are at or near capacity, Sound Transit would implement alternative measures, such as routing transit riders that use these locations to available spaces at nearby park-and-ride lots, such as the Star Lake Park & Ride, or leasing parking lots or new parking areas within the vicinity of the temporarily closed lot.

Operations and Maintenance Facility South

ATTACHMENT G1-1

Transportation Technical Analysis Methodology Memorandum

Federal Transit Administration

SOUNDTRANSIT

1 TRANSPORTATION

1.1 Introduction

This technical analysis methodology memorandum describes the methods and assumptions for preparing the transportation element of the Operations and Maintenance Facility South (OMF South) Environmental Impact Statement (EIS). The analysis of local transportation and system-wide light rail transit impacts will identify and evaluate the impacts of the project alternatives on the following:

- Design year traffic service levels at key intersections affected by the project alternatives
- Short-term impacts to vehicular, bicycle, and pedestrian traffic resulting from construction activities
- Property access, freight and local traffic flow changes caused by street closures and/or modifications
- Safety
- Bicycle and pedestrian circulation
- Transit service

1.2 Guiding Regulations, Plans, and/or Policies

Relevant policies, laws, and regulations that govern or influence the transportation impact analysis include the following:

- Washington State Department of Transportation (WSDOT) Synchro and SimTraffic Protocol, 2018
- WSDOT Traffic Analysis Guidebook
- Cities of Kent and Federal Way Transportation Plans and Capital Improvement Programs
- Level of Service Standards for the City of Kent (Comprehensive Plan, Chapter 4) and City of Federal Way (Comprehensive Plan, Chapter 3), King County (Comprehensive Plan, Chapter 8), and Washington State Highways (Revised Code of Washington [RCW] 47.06.140(2))
- Washington Transportation Plan, Phase 2—Implementation 2017–2040 (WSDOT 2019)
- WSDOT Design Manual
- WSDOT Traffic Manual M 51-20
- Transportation Research Board Highway Capacity Manual (2010)
- AASHTO Highway Safety Manual
- WSDOT Protocol for Vissim Simulation, 2014
- WSDOT Sidra Policy Settings, 2015
- FHWA Guidelines for Applying Traffic Microsimulation Modeling Software
- Puget Sound Regional Council (PSRC), VISION 2040 (PSRC 2009)

- King County Metro Transit, Strategic Plan for Public Transportation, 2011–2021 (King County Metro Transit 2015)
- Pierce Transit Strategic Plan 2015–2020 (Pierce Transit 2015)

1.3 Data Needs and Sources

A variety of data will be collected and assembled to analyze the transportation-related effects of the project alternatives. These data sets will include the following:

- Existing peak-hour turning-movement counts at the intersections identified below under "Intersections to be Studied." These counts will be collected from the City of Kent, City of Federal Way, King County, and WSDOT for the PM peak hour for all locations, and for the AM peak hour for selected locations where AM peak-hour operations are determined to be as, or more, critical than PM peak-hour operations. If, for project construction impacts, data from I-5 is needed, the volume data from WSDOT's loop counters will be used to generate existing mainline and ramp volumes. If year 2016 or more recent turning movement counts are not available from the agencies listed above, new counts will be taken for a 3-hour period during the PM peak hour. The new counts will include automobiles; trucks classified by light, medium, and heavy types; buses; pedestrians; and bicyclists. AM peak-hour turning-movement counts will also be collected where AM peak-hour volumes are the highest or the existing and future traffic issues are considered critical during the AM time period (e.g., if an intersection provides access to a regional facility). These locations will be chosen based on area knowledge, a comparison of available AM versus PM peak-hour traffic volumes, and/or if identified by Sound Transit and local or state agency staff. All peak-hour turning-movement counts will be factored to a common base analysis year (2019) based on available historical data trends.
- Daily traffic counts in the study area, as available from local jurisdictions. These counts will be factored to a common base analysis year (2019).
- Physical characteristics of the existing street system that may be affected by project alternatives.
- Existing transit route information along the proposed project alternatives will be obtained from local transit agencies and compiled. This task will include information on selected bus routes that serve the vicinity of the project alternatives as well as light rail mainline operations.
- Accident data for the most recent available 5-year period will be obtained for the potentially affected intersections in the study area.
- Local, regional, and state agency Six-Year Transportation Improvement Plans/Capital Improvement Programs or Transportation Facilities Plans, as well as other planned improvements in proximity to the project alternatives, will be reviewed and summarized. This effort will include identification of all "committed" improvements assumed for the No-Build Alternative.

1.4 Study Area and Area of Effect

The transportation analysis will include evaluation measures that consider system-wide light rail transit operations as well as localized street intersection impacts in proximity to the project alternatives. Analysis of system-wide light rail transit impacts will address the effects of the project alternatives on light rail transit reliability and operations. The arterial and local street analysis will focus on locations assumed to be most likely affected by the project alternatives. The intersections that will be analyzed are those directly affected, such as by a change in channelization or signal control resulting from light rail lead track crossings and those affected by OMF South traffic volumes near each site.

1.5 Affected Environment

The affected environment for transportation includes components of the transportation system within the affected area. These components include traffic-related operations and performance on roadway facilities; transit, both road-based and light rail; bicycles; and pedestrians in the vicinity of the project alternatives. Effects on the regional light rail transportation system will also be considered. Measures for assessing impacts on these transportation elements, discussed in the following sections, will be both quantitative and qualitative and will be displayed both graphically and in a tabular format as appropriate. Primary issues of concern include impacts on overall mobility for these various modes (e.g., travel times, speeds, and accessibility) as well as reliability and safety. These issues need to be assessed for the construction stages of the proposed project as well as after completion, when the project is fully operational.

1.6 Environmental Impact Analysis

1.6.1 Direct Impacts

Transportation Analysis Years

Based on the project's schedule and available traffic forecasting data, the transportation analysis will focus on two distinct periods:

- Existing—2019.
- Design Year—2042. This year has been identified as the design year for analysis. The 2042 analysis will include evaluation of the No-Build Alternative.

In the absence of available traffic forecasting data, an estimated annual growth in traffic volume consistent with regional and local area plans and historic data will be developed and applied to existing traffic counts to generate reasonable future traffic volumes.

Local Surface Streets

The surface street system analysis will focus on intersection operations and safety analysis. Impacts on property access and circulation, parking, nonmotorized facilities, construction, and safety will be addressed. The methodologies proposed to analyze the surface street system will be described in this section.

Intersection Operations

Effects on intersection operations will be evaluated based on the calculated design year 2042 peak-hour intersection level of service (LOS). LOS measures the quality of traffic operations at an intersection in terms of both operational conditions and motorists' perceptions. LOS ratings range from "A" to "F." LOS A represents the best operation and LOS F the poorest operation.

Agency Thresholds

As part of each agency's comprehensive planning efforts, agency transportation goals and LOS standards are developed. While each agency accepts different levels of congestion, a delay-based intersection LOS analysis has been preliminarily accepted by each agency. Delay is expressed in terms of average delay per vehicle, in seconds, experienced due to the intersection operations. LOS definitions for signalized and unsignalized intersections are included in Table 1-1. Overall, if a given intersection's operations are better than the LOS standard for each agency with the build alternative, then that intersection is considered to meet the agency's standard and does not require mitigation. In situations where the intersection operates worse than the agency's LOS standard without the build alternative, then mitigation is only required if the intersection delay and/or LOS degrades further with the build alternative.

Table 1-1 Agency Level of Service Standards

Agency	LOS Standard
WSDOT	LOS D
Kent	LOS E
Des Moines	LOS D
Federal Way	Signalized v/c < 1.2 Unsignalized v/c < 1.0
King County	LOS E

v/c = volume-to-capacity ratio

Trip Generation

Information on 2042 trip generation for the OMF South facility will reflect employee ingress and egress and deliveries. These traffic volumes will be added to the future No-Build Alternative traffic volumes as the basis on which to analyze the project alternatives. However, employee trips to and from the facility are expected to occur outside of the peak-hour period. Therefore, traffic impacts from vehicular trips generated by the project are expected to be negligible. In locations where the facility will replace an existing land use that generates trips, the Institute of Transportation Engineers Trip Generation Manual will be used to estimate the change in peak trips for the existing land use.

Level of Service Analysis

Synchro (version 10.0) software will be used to determine the projected 2042 AM and PM peak-hour LOS at signalized and unsignalized intersections identified below, under "Intersections to be Studied." The Highway Capacity Manual (HCM) report from the Synchro software will be used to summarize average intersection delay, LOS, and critical queue lengths. The LOS at a signalized intersection will be defined in terms of average intersection delay. Delay is dependent on two factors: 1) the capacity of the intersection as defined by the number of lanes, lane widths, pedestrian volumes, and other features; and 2) signal timing. To provide consistent comparison between project alternatives, the signal timing will be optimized in the Synchro software to provide optimal levels of delay. Capacity, delay, and LOS are calculated for each traffic movement or group of traffic movements at an intersection. The weighted average delay across all traffic movements determines the overall LOS for a signalized intersection.

The LOS at an unsignalized intersection is also defined in terms of delay, but only for the approach that is stop-controlled, which is typically the minor street. For unsignalized intersections that are stop controlled on each approach, the average intersection delay is reported. LOS definitions for signalized and unsignalized intersections are provided in Table 1-2. Default values for the analysis will be developed for intersections where actual values are not available. These will include assumptions with respect to saturation flow rates, geometry, traffic, and signalization conditions.

Table 1-2 Level of Service Thresholds

LOS Rating	Average Delay for Signalized Intersections (seconds/vehicle)	Average Delay for Stop Controlled Intersections (seconds/vehicle)
A	0 – 10	0 – 10
B	> 10 – 20	> 10 – 15
C	> 20 – 35	> 15 – 25
D	> 35 – 55	> 25 – 35
E	> 55 – 80	> 35 – 50
F	> 80	> 50

Intersections to be Studied

A preliminary list of intersection locations has been identified for analysis based on the project alternatives and associated lead track. Each of the intersections listed will be modeled for both the No Build Alternative and the project alternatives. Exhibits 1-1 and 1-2 show the locations of these intersections. The exhibits below represent a preliminary layout of the potential site locations and were developed to illustrate the intersections for analysis relative to possible site access locations. These exhibits should not be used to determine any right-of-way or other impacts.

Property Access and Local Circulation

This area of evaluation will assess local area traffic impacts, including access to properties. The focus will be on impacts during both construction and full build out of the project (2042). The evaluation criteria will include any physical change in access to properties resulting from lead track alternative alignments. In addition to the analysis of intersection LOS and delay impacts, traffic impacts on local circulation will be assessed qualitatively.

Nonmotorized Facilities and Modes

The project alternatives will be qualitatively assessed regarding existing and future pedestrian and bicycle facilities. Specific issues to be discussed and assessed include the following:

- Direct (physical) effects on pedestrian and bicycle facilities in proximity to each project alternative and associated lead track.
- Barriers to nonmotorized (pedestrian and bicycle) traffic movement introduced by the project alternatives.

Transit

The project alternatives will be qualitatively assessed to evaluate:

- System-wide effects on regional light rail operations (e.g., service reliability).
- Local effects to bus or other rail transit services in proximity to the project alternatives.

Construction

Two primary sources of construction impacts on local traffic will be considered from a generally qualitative standpoint:

- Impacts on traffic operations, property access, and parking supply related to potential road, sidewalk, bicycle, or other transportation facility closures during construction.
- Impacts of construction-related traffic on traffic operations.

Construction traffic analysis will consider the following:

- Identification of changes in roadway capacity, including potential lane closure requirements, parking restrictions, pedestrian or bicycle facility impacts, areas of construction activity adjacent to travel lanes, or other reductions to capacity due to transit facility construction activity.
- Impacts on transit and emergency services.
- Impacts on school transportation services during construction.
- Impacts of construction-related activity on on-street parking supply.
- Identification of potential construction staging areas, including access and impact on roadway operations.
- Identification of potential construction access and truck routes and the impact of construction related traffic on these routes.
- Estimation of construction truck traffic.
- Development of mitigation measures.

The analysis will be summarized in a tabular format to identify the following:

- Impact location(s).
- Street characteristics.
- Type of construction activity, including likely duration of impact (short-term versus long-term).
- Level of construction traffic (characterized as high, moderate, or low). High truck traffic is associated with major fill, excavation, and concrete work such as with tunneling. Moderate truck traffic generally refers to activities not associated with major fill or excavation work. Low truck traffic occurs when none of the construction activities associated with moderate or high truck traffic occurs.
- Full or partial road closures.
- Availability of detour routes.
- Potential for detoured traffic to affect a residential neighborhood. This is characterized as high, medium, or low and is related to both potential for road closure and options for traffic detour.
- Loss of on-street parking. This may be characterized as “yes” for parking loss and “no” for no parking loss. Additionally, there may be some temporary loss of off-street parking due to the location and operation of construction staging, as well as construction worker parking.

Safety

Potential effects of the project on safety will be assessed qualitatively for all modes within the study area including general traffic, transit, bicycle, and pedestrian modes. The safety (accident/crash) analysis will use quantitative data to understand existing conditions and locations with potential issues to understand how future alternatives might affect those conditions. The safety analysis will be used to assess accidents currently occurring within the project limits in terms of type, cause, and frequency. Accident data from the latest 3 years will be compiled and summarized to identify any current safety deficiencies. Unique accident patterns (e.g., high frequency of a specific pattern) will be noted. The accident data will be collected for any directly affected local intersections and roadways. An intersection and roadway safety analysis will be conducted only where the project alternatives 1) include at grade lead track in semi-exclusive right-of-way, 2) include elevated track within or immediately adjacent to the road right-of-way, or 3) results in a physical change to a roadway. No accident analysis or safety conclusions for project alternatives proposed to operate outside the roadway right-of-way (exclusive right-of-way) will be conducted other than where (or if) the alternative physically changes the geometry of a roadway. Safety effects on bicycle and pedestrian travel will be assessed based on change in potential conflicts with motorized modes, as well as change in facilities provided for their travel.

1.6.2 Indirect Impacts

Indirect impacts are project effects that occur later in time or some distance from the project. Typical indirect impacts are those associated with changes in land use development patterns, typically consistent with adopted plans and zoning, and those associated with changes in transportation accessibility over time. These effects are described in the land use and specific resource reports, but the potential changes in transportation access that could lead to these effects will be discussed qualitatively.

1.6.3 Cumulative Impacts

The assessment of cumulative impacts related to transportation will include a qualitative evaluation and discussion of past, present, and reasonably foreseeable future actions that could interact with the project alternatives and that were not included in the traffic modeling. These may include, but are not limited to, consideration of effects from actions such as the following:

- Construction activities from other transportation projects that could affect or be influenced by the project construction activities.
- Local developments and public infrastructure projects that could contribute to cumulative traffic delays on local arterial streets over the construction period.

The discussion of cumulative impacts will be developed in coordination with the Federal Way Link Extension project, which is assumed to be part of the No-Build Alternative, and the Tacoma Dome Link Extension project, which is a reasonably foreseeable future project. Other projects that are reasonably foreseeable and will be considered in the cumulative impacts analysis are the SR 509 Completion project and the Federal Way City Center Access project.

1.7 Mitigation Measures

Potential mitigation measures will be described to address potential transportation impacts associated with the project alternatives.

Based on the design year (2042) traffic analysis, opportunities for mitigation of long-term impacts will be identified for intersections that do not meet the established LOS standards. These measures might include operational changes such as signal phasing or timing, or physical modification such as added lanes. For intersections that do not meet the established LOS standards in the No-Build Alternative, the project alternatives are only obligated to bring the operating conditions back to the No-Build condition. Determining if an intersection meets the agency LOS standards will be based on the conditions at each individual intersection. Mitigation measures related to other elements of the transportation analysis such as nonmotorized, parking, and safety will also be described. Mitigation measures aimed at addressing the local construction traffic impacts identified above will be developed and reviewed.

1.8 Proposed Exhibits, Maps, or Other Data

The EIS section will include exhibits illustrating LOS analysis for potentially affected intersections.

1.9 Documentation

For this element, the following documentation will be developed:

- A Transportation EIS section
- A technical report detailing the technical analyses discussed in this memorandum

1.10 Data Developed for Use by Other Disciplines

Noise Effect Analysis Data

If the project alternatives would result in roadway modifications that would increase roadway traffic capacity or move roadway travel lanes closer to sensitive receivers, the following types of data will be produced by the transportation team to support the noise effect analysis:

- AM and PM peak-hour Synchro model files for affected roadway intersections (including vehicle classes).
- The above information will be provided for existing conditions and the design year (2042).

SOUNDTRANSIT

June 2024

Summary

This technical report contains the noise and vibration impact assessment for the Central Puget Sound Regional Transit Authority (Sound Transit) Operations and Maintenance Facility South (OMF South) project. The report follows Federal Transit Administration (FTA) and Sound Transit guidance in evaluating impacts and potential mitigation measures. The FTA noise and vibration guidance has been adopted by Sound Transit in their environmental methodology to assess impacts from transit projects, regardless of the funding source. This technical report is intended to be a supplement to the noise and vibration chapter in the Final Environmental Impact Statement (EIS).

The results of the noise and vibration impact assessment indicate that there would be no FTA noise or vibration impacts from operation of any of the three OMF South alternatives. There would also be no exceedances of the Washington Administrative Code (WAC) from operation of any of the three OMF South alternatives. There would be FTA moderate noise impacts from the 55 mph Design Option for the mainline track for the Preferred or South 344th Street alternatives to the Federal Way Downtown Station. All exceedances and impacts could be mitigated through the implementation of noise barriers.

1 INTRODUCTION

This technical report contains the noise and vibration impact assessment for the Central Puget Sound Regional Transit Authority (Sound Transit) Operations and Maintenance Facility South (OMF South) project. The report follows Federal Transit Administration (FTA) and Sound Transit policies and practices in evaluating impacts and potential mitigation measures. The FTA noise and vibration guidance is used by Sound Transit in their environmental methodology to assess impacts from transit projects.

The report includes a description of the existing noise and vibration conditions near the project alternatives, the noise and vibration assessment for sensitive receptors near the three OMF South alternatives, the noise and vibration assessment for the two mainline track options from the Preferred and the South 344th Street alternatives to the Federal Way Downtown Station, and mitigation options for impacts identified in the assessment.

1.1 Project Description

Sound Transit proposes to construct and operate an operations and maintenance facility in its South Corridor (OMF South) to meet agency needs for an expanded fleet of light rail vehicles (LRVs). The need to expand LRV maintenance capacity was identified in Sound Transit 3: The Regional Transit System Plan for Central Puget Sound (Sound Transit 3). OMF South would be used to store, maintain, and deploy approximately144 LRVs for daily service. It would provide facilities for vehicle storage, inspections, maintenance and repair, interior vehicle cleaning, and exterior vehicle washing. Additionally, the facility would receive, test, and commission new LRVs for the entire light rail system.

OMF South would also be used to accommodate administrative and operational functions, such as serving as a report base for LRV operators. Included is a Maintenance of Way building for maintenance and storage of spare parts for tracks, vehicle propulsion equipment, train signals, and other infrastructure, in addition to storage facilities for the entire Link system. Other facility elements would include employee and visitor parking, operations staff offices, maintenance staff offices, dispatcher work stations, an employee report room, and areas with lockers, showers, and restrooms for both operators and maintenance personnel.

Three site alternatives for the proposed project are evaluated in the Final EIS: two in Federal Way and one in Kent (Figure G2.1-1). These alternatives are named the Preferred Alternative (referred to as the South 336th Street Alternative in the 2021 Draft EIS), the South 344th Street Alternative, and the Midway Landfill Alternative, respectively.

OMF South would need to have tracks connecting to a light rail line that will be operating when the facility is planned to open, which in southern King County is the Federal Way Link Extension (FWLE). The length and location of these connecting tracks varies by alternative. The Preferred Alternative would require the construction of approximately 1.4 miles of mainline tracks and the South 344th Street Alternative would require approximately 1.8 miles of mainline tracks. The Midway Landfill Alternative is adjacent to FWLE and would connect by lead tracks directly to the FWLE mainline tracks. The Preferred and South 344th Street alternative mainlines include tail tracks that extend approximately 1,000 feet past the site to allow trains to turn around and access the site from the south if the northern lead tracks were out of service.

The Preferred and South 344th Street alternative would also include a test track to prepare new vehicles for service. The test track would run east of and parallel to the mainline connecting the sites to FWLE. (Figures G2.1-2 and G2.1-3). Figure G2.1-5 shows the mainline track options. The Midway Landfill Alternative would not include a test track because the varying grades of the existing mainline tracks make it infeasible. Due to this, this analysis assumes that LRV testing would occur on the mainline tracks.

In addition to the features identified above, the Preferred Alternative includes the extension of 18th Place S between S 340th Street and S 336th Street to replace the functions of 20th Avenue S, which would be vacated, and the extension of 21st Ave S south to S 344th Street to meet Federal Way code requirements.

2 NOISE AND VIBRATION BASICS

2.1 Noise Basics

Sound is defined as small changes in air pressure above and below the standard atmospheric pressure, and noise is usually considered to be unwanted sound. The three parameters that define noise include:

- **Level:** The level of sound is the magnitude of air pressure change above and below atmospheric pressure and is expressed in decibels (dB). Typical sounds fall within a range between 0 dB (the approximate lower limit of human hearing) and 120 dB (the highest sound level generally experienced in the environment). A 3-dB change in sound level is perceived as a barely noticeable change outdoors, and a 10-dB change in sound level is perceived as a doubling (or halving) of loudness.
- **Frequency:** The frequency (pitch or tone) of sound is the rate of air pressure change and is expressed in cycles per second, or Hertz (Hz). Human ears can detect a wide range of frequencies from around 20 Hz to 20,000 Hz; however, human hearing is not as sensitive at high and low frequencies, and the A-weighting system, which measures what humans hear in a more meaningful way by reducing the sound levels of higher- and lower-frequency sounds, is used to provide a measure (dBA) that correlates with human response to noise. Figure G2.2-1 shows typical maximum A-weighted sound levels for transit and non-transit sources. The A-weighted sound level has been widely adopted by acousticians as the most appropriate descriptor for environmental noise.
- **Time Pattern:** Because environmental noise is constantly changing, it is common to condense all of this information into a single number, called the equivalent sound level (Leq). The Leq represents the changing sound level over a period of time, typically 1 hour or 24 hours in transit noise assessments. For assessing the noise impact of rail projects at residential land uses, the day-night sound level (Ldn) is the noise descriptor commonly used, and it has been adopted by many agencies as the best way to describe how people respond to noise in their environment. Ldn is a 24-hour cumulative A-weighted noise level that includes all noises that occur during a day, with a 10-dB penalty for nighttime noise (10 p.m. to 7 a.m.). This nighttime penalty means that any noise events at night are equivalent to 10 similar events during the day.

Typical Ldn values for various transit operations and environments are shown on Figure G2.2-2.

In addition to the Leq and Ldn, there are other metrics used to describe noise. The loudest 1 second of noise over a measurement period, or maximum A-weighted sound level (Lmax), is used in many local and state ordinances for noise emitted from private land uses and for construction noise impact evaluations. Environmental noise can also be viewed on a statistical basis using percentile sound levels (Ln), which refer to the sound level exceeded n-percent of the time.

2.2 Vibration Basics

Ground-borne vibration from trains refers to the fluctuating or oscillatory motion experienced by persons on the ground and in buildings near railroad tracks. Vibration can be described in terms of displacement, velocity, or acceleration. Displacement is generally the easiest descriptor to understand. For a vibrating floor, the displacement is simply the distance that a point on the floor moves away from its static position. Velocity represents the instantaneous speed of the floor movement, and acceleration is the rate of change of the speed. Although displacement is easier to understand, the response of humans, buildings, and equipment to vibration is more accurately described using velocity or acceleration.

Two methods are used for quantifying vibration. The peak particle velocity (PPV) is defined as the maximum instantaneous positive or negative peak of the vibration signal. PPV often is used in the monitoring of blasting vibration, since it is related to the stresses experienced by buildings. Although PPV is appropriate for evaluating the potential of building damage, it is not suitable for evaluating human response. It takes some time for the human body to respond to vibration impulses. In a sense, the human body responds to an average of the vibration amplitude. Because the net average of a vibration signal is zero, the root mean square (RMS) amplitude is used to describe the "smoothed" vibration amplitude.

PPV and RMS velocities are normally described in inches per second in the U.S. and in meters per second in the rest of the world. Decibel notation is in common use for vibration and has been adopted by the FTA in their guidance. Decibel notation compresses the range of numbers required to describe vibration. Vibration levels in this report are referenced to 1 x 10^{-6} inches per second (in/sec). The abbreviation “VdB” is used in this document for vibration decibels to reduce the potential for confusion with sound decibels. Common vibration sources and human and structural response to ground-borne vibration are illustrated in Figure G2.2-3. Typical vibration levels can range from below 50 VdB to 100 VdB (0.000316 in/sec to 0.1 in/sec). The human threshold of perception is approximately 65 VdB.

Ground-borne vibration can lead to ground-borne noise, which is a low-volume, low-frequency rumble inside buildings, resulting when ground vibration causes the flexible walls of the building to resonate and generate noise. Ground-borne noise is normally not a consideration when trains are elevated or at grade. In these situations, the airborne noise usually overwhelms ground-borne noise, so the airborne noise level is the major consideration. However, ground-borne noise becomes an important consideration where there are sections of the corridor that are in a tunnel or where sensitive interior spaces are well isolated from the airborne noise. In these situations, airborne noise is not a major path and ground-borne noise becomes the most important path into the building. In unusual situations, ground-borne noise may also need to be considered in cases where the airborne noise from a project is mitigated by a sound wall.

3 IMPACT ASSESSMENT METHODOLOGY

Noise and vibration from facility and mainline track operations were modeled using the methods described in the FTA guidance manual. Noise-generating activities would include vehicles moving within the OMF South facility, vehicle washing and drying, a traction power substation, vehicles moving on the mainline track (for the Preferred Alternative and the 344th Street Alternative) into service in the morning and back to the facility in the late evening, and operations on the test track. The only activity that would generate vibration would be LRVs moving on the mainline and test track options for the Preferred and the South 344th Street alternatives. The assessment described below, including all operational assumptions, is for the OMF South project only, and does not include the Tacoma Dome Link Extension (TDLE) project, which will be assessed in a separate EIS. Anticipated noise impacts from TDLE are discussed in the cumulative impacts section.

3.1 Operational Noise Assessment Methodology

3.1.1 OMF Site Noise Assessment Methodology

The OMF South noise assessment methodology was identical for each of the three alternatives. The reference noise levels were taken from the OMF East noise and vibration technical report (Sound Transit 2015), the FTA guidance manual, and the Sound Transit reference noise and vibration level report. The assessment assumes that the majority of the operations activities occur at night, when the LRVs are not in revenue service. The noise assessment includes the following assumptions:

- For the Preferred and South 344th Street alternatives, 104 LRVs would be based at the facility; 26 four-car LRVs would depart to the north before 7 a.m. and return after midnight. With the inclusion of TDLE, the number of LRVs based at the facility would increase to approximately 144; operations would also increase. The results of that assessment are covered in Section 7, Cumulative Impacts.
- For the Midway Landfill Alternative, 104 LRVs would be based at the facility; 13 four-car LRVs would depart to the north and 13 four-car LRVs would depart to the south before 7 a.m. and return after midnight. With the inclusion of TDLE, the number of LRVs based at the facility would increase to approximately 144; operations would also increase. The results of that assessment are covered in Section 7, Cumulative Impacts.
- LRVs would travel at 7 mph within the boundaries of the site. A four-car LRV traveling at 7 mph on ballast and tie tracks would generate a sound exposure level of 77.2 dBA at 50 feet.
- All LRVs would be washed each night inside the wash building. Each four-car train takes approximately 10 minutes to be washed, and the maximum noise level for the washers is 74 dBA at 50 feet from the blower end of the wash facility (Sound Transit 2015).
- Maintenance activities would take place inside the shop building and would not generate substantial noise levels.
- Wheel squeal is possible on curves with a radius of less than 600 to 1,000 feet depending on the speed and type of trackway. Wheel squeal is not included in the noise model because Sound Transit has committed to reducing any potential wheel squeal by installing wayside lubricators on all curves in noise-sensitive areas with a radius of less than 600 feet and by preparing all curves for wayside lubricators that have a radius of between 600 and 1,000 feet.

- The slow speeds within the OMF South alternatives would reduce any impact noise associated with crossovers within the facility. Crossovers connecting to the mainline tracks would have higher speed operations and the potential for additional noise from vehicles traveling over them.
- Limited testing of LRV train-mounted bells or horns would occur during the daytime.
- The traction power substation would generate a maximum noise level of 49 dBA at a distance of 50 feet and would operate 24 hours per day (Sound Transit 2015).

3.1.2 Mainline and Test Track Noise Assessment Methodology

For the Preferred and the South 344th Street alternatives, trains would depart to the north on the mainline track to the Federal Way Downtown Station. The projection of noise levels from light rail operations at sensitive receptors was determined using the model specified in the FTA guidance manual and current design of the proposed project, with the following assumptions:

- For the Preferred and South 344th Street alternatives, 26 four-car LRVs would depart on the mainline track to the north before 7 a.m. and return after midnight.
- For the test track, eight one-car LRVs would make roundtrips per hour for 4 hours during the daytime and 6 hours during the nighttime.
- LRV train speeds will be 25 mph on the mainline track and 55 mph on the test track.
- The sound exposure level (SEL) for four-car LRV trains on at-grade ballast and tie tracks traveling at 25 mph would be 82.7 dBA at 50 feet (Sound Transit 2019).
- The SEL for one-car LRV trains on at-grade ballast and tie tracks traveling at 55 mph would be 80.1 dBA at 50 feet (Sound Transit 2019).
- The SEL for one- and four-car LRV trains on direct fixation tracks on a concrete structure are increased by 4 dB relative to ballast and tie tracks (Sound Transit 2019).
- Locations of elevated structures, crossovers, and ballast and tie track were identified based on plan and profile maps provided. No crossovers are located on the mainline track other than where they connect with the lead track and test track.

3.1.3 Noise Measurement Procedures and Equipment Methodology

The noise measurement program consisted of long-term (24-hour) monitoring of the A-weighted sound level. All the measurement sites were located in or near noise-sensitive areas and were selected to represent a range of existing noise conditions near the OMF South alternatives and mainline track. Long-term noise measurements were conducted at eight locations near the three alternatives and mainline track. The noise measurement locations are shown in Figures G2.5-1 through G2.5-3, photographs of the measurement sites are included in Attachment G2-1, and detailed noise measurement data are presented in Attachment G2-2. Summary information regarding the noise measurements for each OMF South alternative and the mainline track is presented below in Sections 5.2.1.1 through 5.2.1.4.

At each of the measurement sites, the A-weighted sound levels were continuously monitored during the measurement periods. The noise measurements were performed with NTi Audio Model XL2 noise monitors that conform to American National Standards Institute Standard S1.4 for Type 1 (Precision) sound level meters. Calibrations, traceable to the U.S. National Institute of Standards and Technology, were carried out in the field before and after each set of measurements using an acoustical calibrator.

In all cases, the measurement microphone was protected by a windscreen and supported on a tripod at a height of 4 to 6 feet above the ground and was positioned to characterize the exposure of the site to the dominant noise sources in the area. For example, microphones were located at the approximate setback lines of the receptors from adjacent roads and were positioned to avoid acoustic shielding by landscaping, fences, or other obstructions.

3.2 Operational Vibration Assessment Methodology

The projection of ground-borne vibration from train operations was carried out using the model specified in the FTA guidance manual, supplemented by LRV vibration measurement data provided by Sound Transit, with the following assumptions:

- For the Preferred and South 344th Street alternatives, 26 four-car LRVs would depart on the mainline track options to the north before 7 a.m. and return after midnight.
- Vibration source (force density) levels were based on test data provided in the Sound Transit reference noise and vibration level report for both ballast and tie tracks and direct fixation tracks. The vehicle force density includes a 3 VdB safety factor.
- A vibration propagation test was conducted at a location near the mainline track options, as described in Section 3.2.1. The result of this test was combined with the LRV vibration source level measurement data to provide projections of vibration levels from trains operating on the mainline track. For the impact assessment, a 3 VdB safety factor has been added to the vibration test results.
- Vehicle operating speeds on the mainline track would be 25 mph and 55 mph on the test track.
- Locations of elevated structures, crossovers, and ballast and tie track were identified based on plan and profile maps.
- Vibration levels are reduced by 10 VdB for operations on elevated structures.

The assumed vehicle vibration characteristics are represented by the force density levels (FDL) spectra at 25 mph in Figure G2.3-1 for both ballast and tie tracks and direct fixation tracks. The force density is the vehicle input force, by frequency, which is measured for vehicles operating on different track structures. The results were combined with the ground vibration propagation test results (represented by transfer mobility spectra shown in Attachment G2-3) to project vibration levels as a function of distance. The formula for calculating the future vibration levels is as follows:

$$Lv = FDL + LSTM$$

Where:

Lv = projected train vibration level,
FDL = vehicle force density, and
LSTM = line source transfer mobility at a given site.

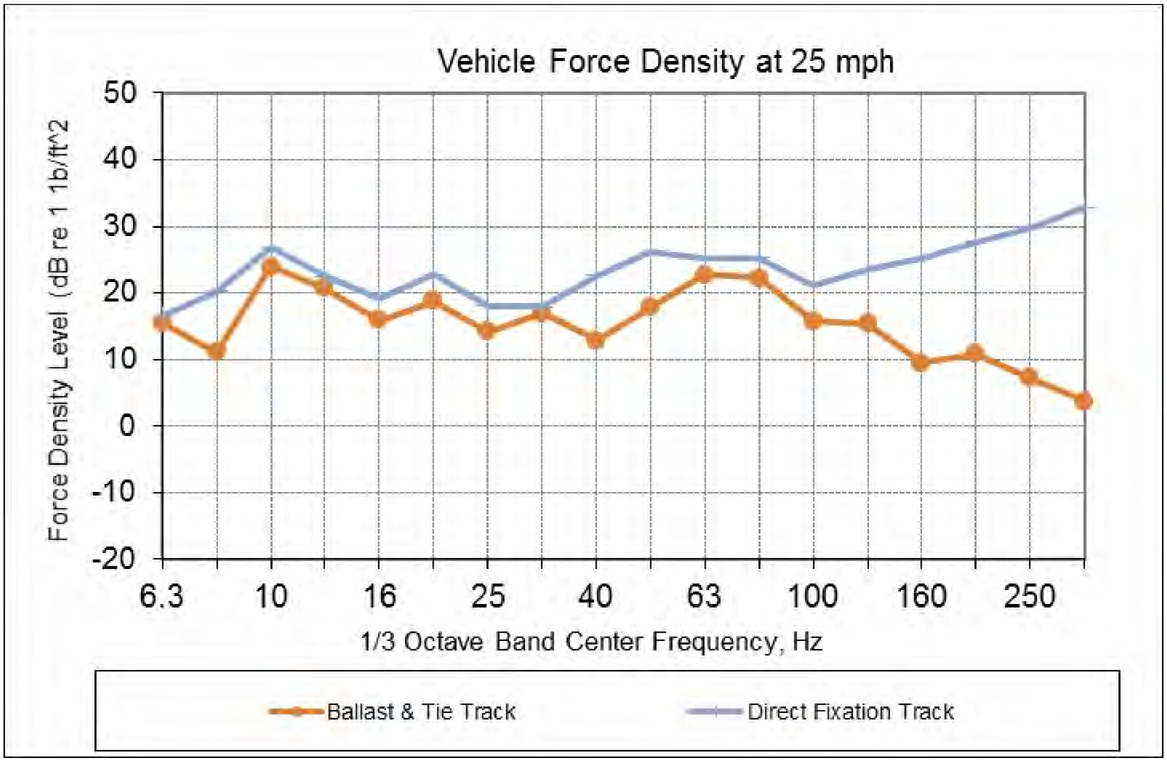

Figure G2.3-1 Vehicle Force Density Levels at 25 mph

3.2.1 Vibration Measurement Procedures Methodology

A vibration propagation measurement was conducted during November 2019 to determine the vibration response characteristics of the ground near vibration-sensitive locations close to the proposed mainline track design options. A custom-built instrumented hammer was used to impart an impulsive force to the ground to determine the ground response. The magnitude of the force was calculated based on the acceleration and mass of the falling hammer. The resulting vibration signals were measured using high-sensitivity accelerometers (PCB Models 393C and 393B05) mounted in a vertical direction on pavement or on steel spikes driven into the ground. The signals from the hammer and accelerometers were recorded using Data Translation DT9837A digital acquisition hardware. Data Translation's QuickDAQ software, running on a laptop computer, was used to review the measurement data.

The vibration propagation test procedure is shown schematically in Figure G2.3-2. The instrumented hammer was used to generate impulses at specific locations spaced 15 feet apart along a line on or parallel to the proposed alignment. A line of accelerometers was placed perpendicular to the line of impacts, as shown in the figure. The relationship between the input force and the resulting vibration measured by the accelerometers, called the transfer mobility, was calculated using proprietary software in the Cross-Spectrum Acoustics laboratory. The transfer mobility represents the vibration propagation characteristics of the ground at the measurement site and along the mainline track design options.

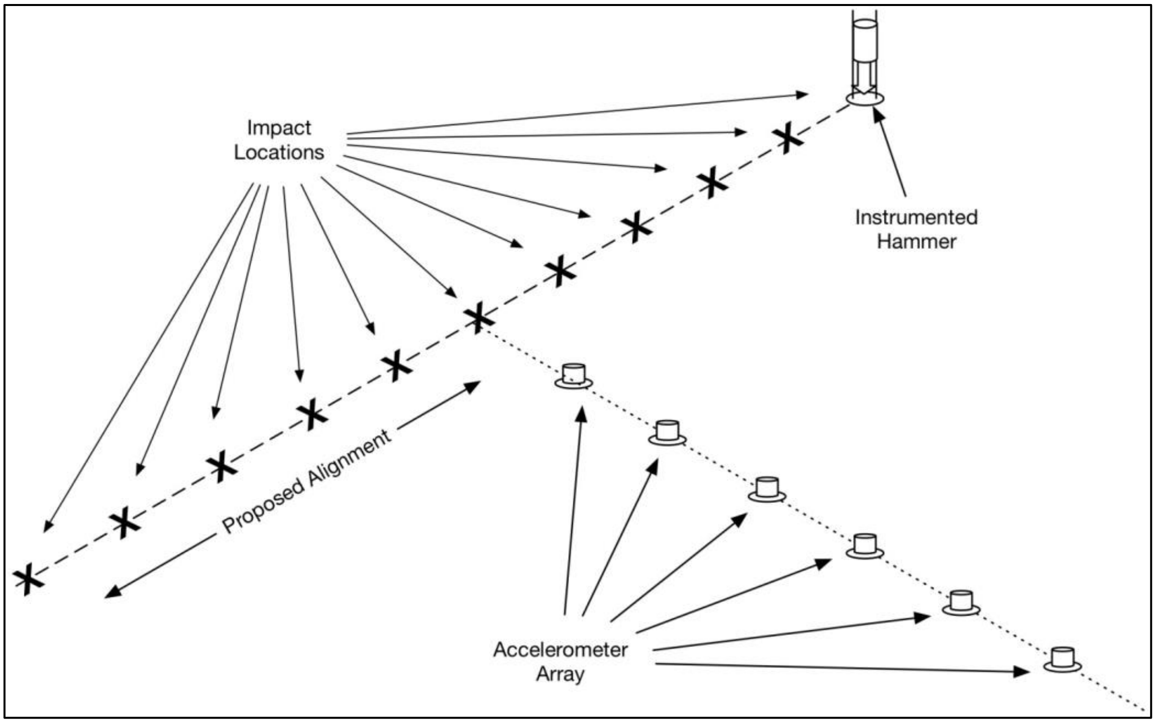

Figure G2.3-2 Vibration Propagation Measurement Schematic

3.3 Construction Noise Assessment Methodology

Construction noise and impacts are assessed using a combination of the methods and construction source data contained in the FTA guidance manual and the Federal Highway Administration (FHWA) Roadway Construction Noise Model from the FHWA Construction Noise Handbook (FHWA 2006). Typical noise levels generated by representative pieces of equipment are listed in Table G2.3-1. The noise exposure at a receiver location may be calculated using decibel addition of all operating construction equipment using the following equation:

$$Leq(n) = Lmax + 10 \times Log(U.F.) - 20 \times Log(D/50) - A_{shielding}$$

where:

Leq(n) = noise exposure at a receiver resulting from the operation of a single piece of equipment over n hours,
Lmax = noise emission level of the particular piece of equipment at the reference distance of 50 feet (taken from Table G2.3-1),
$A_{shielding}$ = shielding provided by barriers, building, or terrain,
D = distance from the receiver to the piece of equipment in feet, and
U.F. = usage factor that accounts for the fraction of time that the equipment is in use over the specified time period. For Leq (1) assume a U.F. equal to 100%, and for 8 hours or more use the values in Table G2.3-1.

The combination of noise from several pieces of equipment operating during the same time period is obtained from decibel addition of the Leq of each single piece of equipment calculated using the above equations.

Table G2.3-1 Construction Equipment Noise Emission Levels

Equipment	Typical Noise Level (dBA) 50 Feet	Usage Factor (U.F.), %
Air compressor	80	40
Backhoe	80	40
Ballast equalizer	82	50

3.4 Construction Vibration Assessment Methodology

Construction vibration is assessed for areas where there is potential for impact from construction activities. Such activities include blasting, pile driving, demolition, and drilling or excavation in close proximity to sensitive structures. Typical vibration levels generated by representative pieces of equipment are listed in Table G2.3-2. For damage assessment, the following equation is used:

$$PPV_{equip} = PPV_{ref} \times [(25/D)]^{\wedge}1.5$$

where:

PPV_{equip} = the peak particle velocity in in/sec of the equipment adjusted for distance,
PPV_{ref} = the reference vibration level in in/sec at 25 feet from Table G2.3-2, and
D = the distance from the equipment to the receiver in feet.

For annoyance assessment, the following equation is used:

$$Lv\ (D) = Lv\ (25\ ft) - 30 \times Log(D/25)$$

where:

Lv(D) = RMS vibration level at distance D,
Lv(25 ft) = RMS vibration level at 25 feet from Table G2.3-2, and
D = the distance from the equipment to the receiver in feet.

Table G2.3-2 Construction Equipment Vibration Source Levels

Equipment	PPV at 25 Feet (in/sec)	Approximate Level 1 at 25 Feet (VdB)
Pile driver (impact) – upper range	1.518	112
Pile driver (impact) – typical	0.644	104
Pile driver (vibratory) – upper range	0.734	105
Pile driver (vibratory) – typical	0.170	93
Clam shovel drop (slurry wall)	0.202	94
Hydromill (slurry wall) – in soil	0.008	66
Hydromill (slurry wall) – in rock	0.017	75
Vibratory roller	0.210	94
Hoe ram	0.089	87

(1) RMS velocity in decibels (VdB) re 1 micro-inch/second.

4 IMPACT CRITERIA

4.1 FTA Operational Noise Impact Criteria

The FTA operational noise impact criteria are based on well-documented research on community response to noise and are based on both the existing level of noise and the change in noise exposure due to a project. The FTA noise criteria compare the project noise with the existing noise (not the No-Build noise). This is because comparison of a noise projection with an existing noise condition is more accurate than comparison of a projection with another noise projection. Because background noise may increase by the time the project is operational, this approach of using existing noise conditions can possibly overestimate the number of impacts.

The FTA noise criteria are based on the land use category of the sensitive receptor. The descriptors and criteria for assessing noise impact vary according to land use categories adjacent to the project. For Category 2, land uses where people live and sleep (e.g., residential neighborhoods, hospitals, and hotels), the Ldn is the assessment parameter. For other land use types (Category 1 or 3) where there are noise-sensitive uses (e.g., outdoor concert areas, schools, and libraries), the Leq for an hour of noise sensitivity that coincides with train activity is the assessment parameter. Table G2.4-1 summarizes the three land use categories.

Table G2.4-1 Land Use Categories and Metrics for Transit Noise Impact Criteria

Land Use Category	Land Use Type	Noise Metric (dBA)	Description of Land Use Category
1	High Sensitivity	Outdoor Leq(h) [1]	Land where quiet is an essential element of its intended purpose. Example land uses include preserved land for serenity and quiet, outdoor amphitheaters and concert pavilions, and National Historic Landmarks with considerable outdoor use. Recording studios and concert halls are also included in this category.
2	Residential	Outdoor Ldn	This category is applicable to all residential land use and buildings where people normally sleep, such as hotels and hospitals.
3	Institutional	Outdoor Leq(h) [1]	This category is applicable to institutional land uses with primarily daytime and evening use. Example land uses include schools, libraries, theaters, and churches, where it is important to avoid interference with such activities as speech, meditation, and concentration on reading material. Places for meditation or study associated with cemeteries, monuments, museums, campgrounds, and recreational facilities are also included in this category.

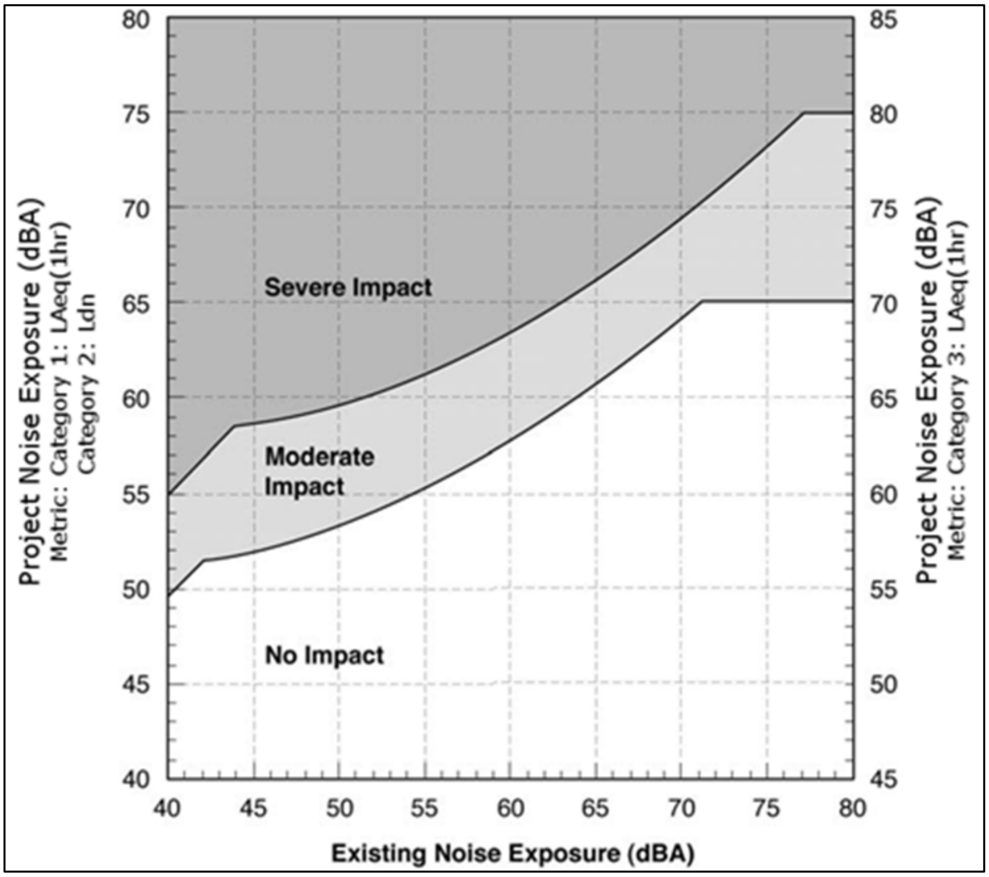
Source: FTA 2018

Note:

(1) Leq (1hr) for the loudest hour of project-related activity during hours of noise sensitivity.

The noise impact criteria are defined by the two curves in Figure G2.4-1, which allow increasing project noise as existing noise levels increase, up to a point at which impact is determined based on project noise alone. The FTA noise impact criteria include three levels of impact, as shown on Figure G2.4-1. The three levels of impact include:

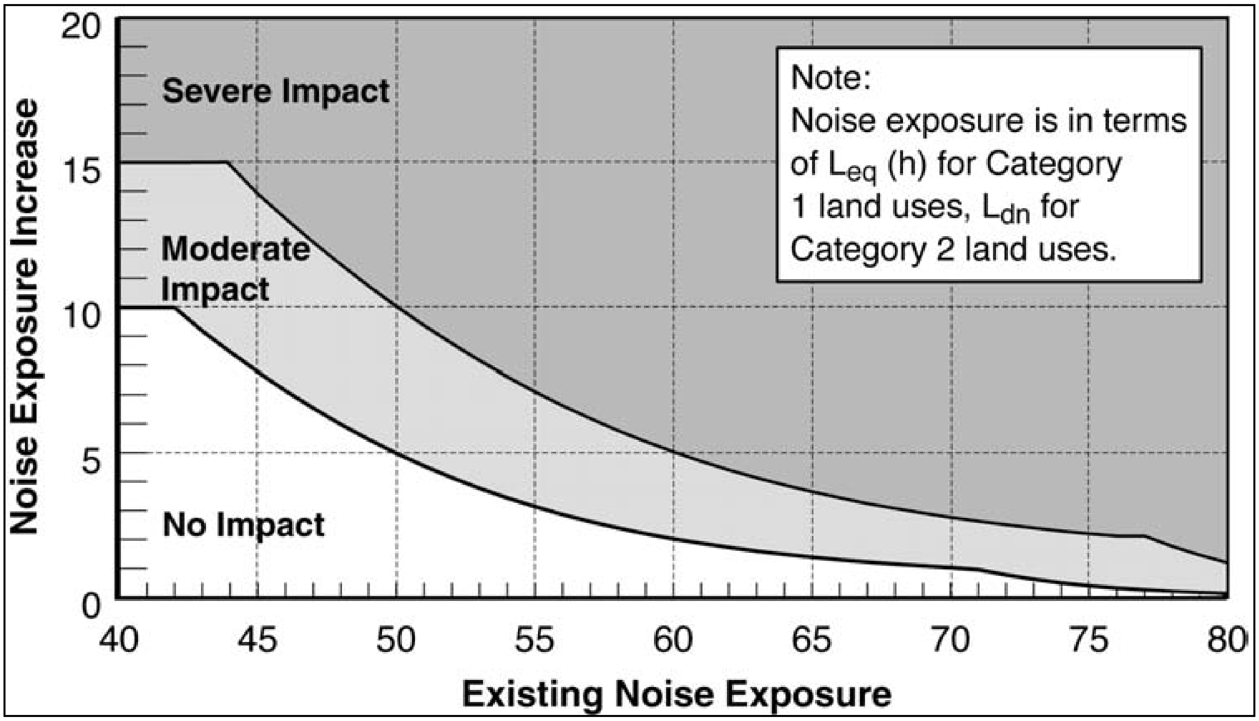
- **No Impact:** In this range, the project is considered to have no impact since, on average, the introduction of the project will result in an insignificant increase in the number of people highly annoyed by the new project noise.
- **Moderate Impact:** Project-generated noise in this range is considered to cause impact at the threshold of measurable annoyance. Moderate impacts serve as an alert to project planners for potential adverse impacts and complaints from the community. Mitigation should be considered at this level of impact based on project specifics and details concerning the affected properties.
- **Severe Impact:** Project-generated noise in this range is likely to cause a high level of community annoyance. Noise mitigation should be applied for severe impacts where feasible.



Source: FTA 2018

Figure G2.4-1 FTA Noise Impact Criteria

Although the curves in Figure G2.4-1 are defined in terms of the project noise exposure and the existing noise exposure, the increase in the cumulative noise — when project-generated noise is added to existing noise levels — is the basis for the criteria. To illustrate this point, Figure G2.4-2 shows the noise impact criteria for Category 1 and Category 2 land uses in terms of the allowable increase in the cumulative noise exposure. Because Ldn and Leq are measures of total acoustic energy, any new noise source in a community will cause an increase, even if the new source level is lower than the existing level. In Figure G2.4-2, the criterion for a moderate impact allows a noise exposure increase of 10 dB if the existing noise exposure is 42 dBA or less, but only a 1 dB increase when the existing noise exposure is 70 dBA.



Note: Noise exposure is in terms of L_{eq} (h) for Category 1 land uses, L_{dn} for Category 2 land uses.

Source: FTA 2018

Figure G2.4-2 FTA Cumulative Noise Impact Criteria

As the existing level of ambient noise increases, the allowable level of transit noise increases, but the total amount that community noise exposure is allowed to increase is reduced. This accounts for the unexpected result that a project noise exposure that is lower than the existing noise exposure can still cause an effect.

4.2 FTA Operational Vibration Impact Criteria

The operational vibration impact criteria used for the project are based on the information contained in Section 6 of the FTA Transit Noise and Vibration Impact Assessment Manual (FTA 2018). The criteria for a general vibration assessment are based on land use and train frequency, as shown in Table G2.4-2. Some buildings, such as concert halls, recording studios, and theaters, can have a higher sensitivity to vibration (or ground-borne noise) but do not fit into the three vibration categories listed below in Table G2.4-2. Because of the sensitivity of these buildings, special attention is paid to these buildings during the environmental assessment of a project.

Table G2.4-2 Ground-Borne Vibration and Noise Impact Criteria for General Assessment

Land Use Category	Ground-Borne Vibration Impact Levels for Frequent Events [1,3]	Ground-Borne Vibration Impact Levels for Occasional Events [1,4]	Ground-Borne Vibration Impact Levels for Infrequent Events [1,5]	Ground-Borne Noise Impact Levels for Frequent Events [2,3]	Ground-Borne Noise Impact Levels for Occasional Events [2,4]	Ground-Borne Noise Impact Levels for Infrequent Events [2,5]
Category 1: Buildings where vibration would interfere with interior operations	65 [6]	65 [6]	65 [6]	N/A [7]	N/A [7]	N/A [7]
Category 2: Residences and buildings where people normally sleep	72	75	80	35	38	43
Category 3: Institutional land uses with primarily daytime use	75	78	83	40	43	48

Source: FTA 2018

Notes:

(1) Ground-borne vibration impact levels = VdB re 1 micro-inch/sec.

(2) Ground-borne noise impact levels = dBA re 20 micro Pascals.

(3) “Frequent Events” is defined as more than 70 vibration events of the same source per day. Most rapid transit projects fall into this category.

(4) “Occasional Events” is defined as between 30 and 70 vibration events of the same source per day. Most commuter trunk lines have this many operations.

(5) “Infrequent Events” is defined as fewer than 30 vibration events of the same kind per day. This category includes most commuter rail branch lines.

(6) This criterion limit is based on levels that are acceptable for most moderately sensitive equipment, such as optical microscopes. Vibration-sensitive manufacturing or research will require detailed evaluation to define the acceptable vibration levels. Ensuring lower vibration levels in a building often requires special design of the HVAC systems and stiffened floors.

(7) Vibration-sensitive equipment is generally not sensitive to ground-borne noise.

Table G2.4-3 shows the FTA criteria for acceptable levels of vibration for several types of special buildings.

Table G2.4-3 Ground-Borne Vibration and Noise Impact Criteria for Special Buildings

Land Use Category	Ground-Borne Vibration Impact Levels for Frequent Events [1,3]	Ground-Borne Vibration Impact Levels for Occasional or Infrequent Events [1,4]	Ground-Borne Noise Impact Levels for Frequent Events [2,3]	Ground-Borne Noise Impact Levels for Occasional or Infrequent Events [2,4]
Concert halls	65	65	25	25
TV studios	65	65	25	25
Recording studios	65	65	25	25
Auditoriums	72	80	30	38
Theaters	72	80	35	43

Source: FTA 2018

Notes:

(1) Ground-borne vibration impact levels = VdB re 1 micro-inch/sec.

(2) Ground-borne noise impact levels = dBA re 20 micro Pascals.

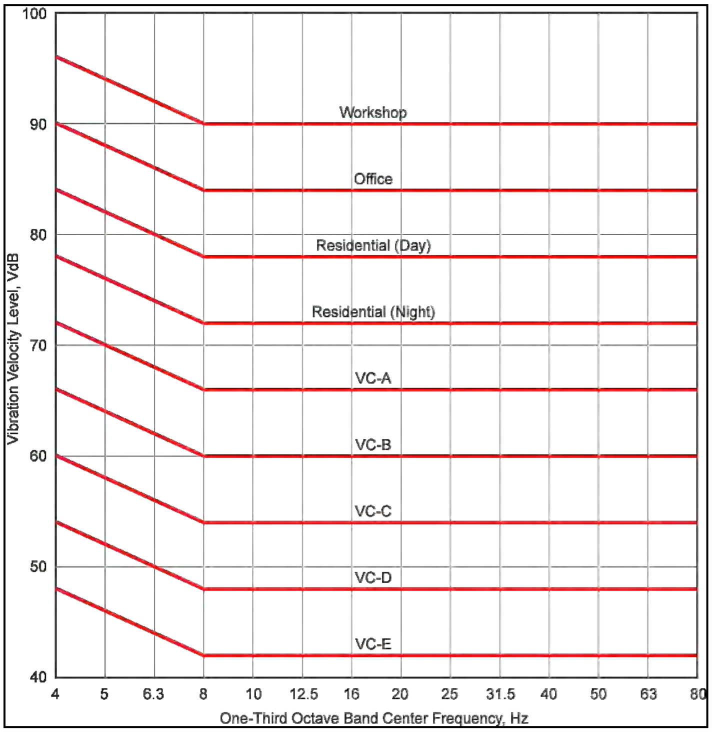
(3) “Frequent Events” is defined as more than 70 vibration events of the same source per day. Most rapid transit projects fall into this category.

(4) “Occasional or Infrequent Events” is defined as fewer than 70 vibration events per day. This category includes most commuter rail system. If the building will rarely be occupied when the trains are operating, there is no need to consider impact. As an example, consider locating a commuter rail line next to a concert hall. If no commuter trains would operate after 7 p.m., it should be rare that the trains interfere with the use of the hall.

Table G2.4-2 and Table G2.4-3 also include additional criteria for ground-borne noise, which is a low-frequency noise that is radiated from the motion of room surfaces, such as walls and ceilings, in buildings due to ground-borne vibration. Ground-borne noise is defined in terms of dBA, which emphasizes middle and high frequencies and is more audible to human ears. The criteria for ground-borne noise are much lower than for airborne noise to account for the low-frequency character of ground-borne noise; however, because airborne noise typically masks ground-borne noise for above ground (at-grade or elevated) transit systems, ground-borne noise is assessed only for operations in tunnels, where airborne noise is not a factor, or at locations such as recording studios, which are well insulated from airborne noise.

The criteria for a detailed vibration assessment are shown in Figure G2.4-3, and descriptions of the curves are shown in Table G2.4-4. The curves in Figure G2.4-3 are applied to the projected vibration spectrum for the project. If the vibration level at any one frequency exceeds the criteria, there is an impact. Conversely, if the entire proposed vibration spectrum of the project is below the curve, there will be no impact.

For the project, the detailed vibration assessment criteria will be used to assess operational ground-borne vibration, except at special buildings where the general vibration assessment criteria will be used.



Source: FTA 2018

Figure G2.4-3 FTA Detailed Vibration Criteria

Table G2.4-4 Interpretation of Vibration Criteria for Detailed Analysis

Criterion Curve (See Figure 3-3)	Max. Level (VdB) [1]	Description of Use
Workshop	90	Vibration that is distinctly felt. Appropriate for workshops and similar areas not as sensitive to vibration.
Office	84	Vibration that can be felt. Appropriate for offices and other areas not as sensitive to vibration.
Residential Day	78	Vibration that is barely felt. Adequate for computer equipment and low-power optical microscopes (up to 20X).
Residential Night, Operating Rooms	72	Vibration is not felt, but ground-borne noise may be audible inside quiet rooms. Suitable for medium-power optical microscopes (100X) and other equipment of low sensitivity.
VC-A	66	Adequate for medium- to high-power optical microscopes (400X), microbalances, optical balances, and similar specialized equipment.
VC-B	60	Adequate for high-power optical microscopes (1000X) and inspection and lithography equipment to 3-micron line widths.
VC-C	54	Appropriate for most lithography and inspection equipment to 1-micron detail size.
VC-D	48	Suitable in most instances for the most demanding equipment, including electron microscopes operating to the limits of their capabilities.
VC-E	42	The most demanding criterion for extremely vibration-sensitive equipment.

Source: FTA 2018

Note:

(1) As measured in 1/3-octave bands of frequency over the frequency range 8 to 80 Hz.

4.3 FTA Construction Noise Impact Criteria

FTA has developed methods for evaluating construction noise levels. These methods are not standardized criteria, but they include noise impact guidelines for sensitive land uses that describe levels having the potential to result in a negative community reaction. Table G2.4-5 shows the FTA noise assessment criteria for construction. The last column applies to construction activities that extend over 30 days near any given receiver. The Ldn is used to assess impacts in residential areas and 24-hour Leq is used in commercial and industrial areas. The 8-hour Leq and the 30-day average Ldn noise exposure from construction noise calculations use the noise emission levels of the construction equipment, their location, and operating hours. The construction noise limits are normally assessed at the noise-sensitive receiver property line.

Table G2.4-5 FTA Construction Noise Criteria

Land Use	8-Hour Leq, dBA Day	8-Hour Leq, dBA Night	Noise Exposure, dBA 30-Day Average
Residential	80	70	75
Commercial	85	85	80
Industrial	90	90	85

Source: FTA 2018

4.4 FTA Construction Vibration Impact Criteria

In addition to the vibration criteria for human annoyance and interference with equipment and spaces described above, there are also vibration criteria for building damage from construction activities. Typical transit operations do not have the potential for damage, so only certain construction activities are assessed for their potential to generate vibration that could cause building damage.

The thresholds for damage to structures are typically several orders of magnitude above the thresholds for human response to vibration. Table G2.4-6 shows the FTA criteria for vibration damage to structures. This is based on the structure and construction type (and not a designation as historic). Table G2.4-6 includes criteria in both VdB and PPV.

Table G2.4-6 FTA Construction Vibration Damage Criteria

Building Category	PPV (in/sec)	Approximate Level [1] (VdB)
I. Reinforced-concrete, steel, or timber (no plaster)	0.5	102
II. Engineered concrete and masonry (no plaster)	0.3	98
III. Non-engineered timber and masonry buildings	0.2	94
IV. Buildings extremely susceptible to vibration damage	0.12	90

Source: FTA 2018

Note:

(1) RMS velocity in VdB re 1 micro-inch/second.

4.5 Traffic Noise Criteria

OMF South does not include any modifications to existing highways that would change the vertical or horizontal alignment or add new lanes. The Preferred Alternative would remove 21st Avenue S between S 336th Street and S 341st Place, extend 18th Avenue S between S 340th Street and S 336th Street, and extend 21st Avenue S south to S 344th Street. However, these new and extended roadways would not be located near sensitive receptors nor have the traffic volumes to increase noise levels to the extent that a noise study would be warranted. Vehicle traffic within the OMF sites was assessed using FTA noise impact criteria, along with other project components.

As required by the FTA, the criteria for determining traffic noise impacts associated with OMF South are taken from the FHWA Procedures for Abatement of Highway Traffic Noise and Construction Noise, Code of Federal Regulations Title 23, § 772 (2010). A traffic noise impact occurs if predicted traffic noise levels approach the criteria levels for specific FHWA land use activity categories or substantially exceed existing noise levels (e.g., a 10-dBA increase). These levels are defined as noise abatement criteria (NAC) and are based on hourly Leq noise levels during the peak traffic noise hour. The land use activity categories of greatest concern in the OMF South study areas are Types B and C, which include residences, playgrounds, active sports areas, parks, schools, churches, libraries, and hospitals. The noise abatement criterion used to determine impacts on this land use is to approach, or exceed, 67 dBA Leq outside of buildings. Under Washington State Department of Transportation (WSDOT) policy, a traffic noise impact occurs if predicted noise levels approach within 1 dB of the NAC. Therefore, an impact on Type B or C land uses would occur at 66 dBA Leq. Some commercial uses, including hotels and motels, have a criterion of 71 dBA under the WSDOT policy. Many other commercial uses, such as general offices and retail businesses, are not normally considered noise-sensitive.

4.6 Local Ordinances

The Washington Administrative Code (WAC) noise regulations (which have been adopted by the cities of Federal Way and Kent) are taken from Chapter 173-60, Maximum Environmental Noise Levels. The noise control ordinance provides three different Environmental Designations for Noise Abatement based on zoning, which are defined as residential, commercial, and industrial. The ordinance is then written to define the maximum allowable noise level from one designation to another. For example, the noise caused by an industrial use, like the proposed project, must be less than 60 dBA at the closest residential property line, 65 dBA at the closest commercial use, and 70 dBA at the closest industrial use. These noise levels apply to stationary land uses, like the OMF South, with noises originating from outside public roadways and rights-of-way. Table G2.4-7 provides the property line noise standards provided in the WAC.

Table G2.4-7 Washington State Noise Control Regulation

Source of Noise	Maximum Allowable Sound Level (Leq, dBA)[1] Residential Receiver	Maximum Allowable Sound Level (Leq, dBA)[1] Commercial Receiver	Maximum Allowable Sound Level (Leq, dBA)[1] Industrial Receiver
Residential	55	57	60
Commercial	57	60	65
Industrial	60	65	70

Note:

(1) Between 10 p.m. and 7 a.m., the levels given above are reduced by 10 dB for residential receiving property.

In addition to the property-line noise standards listed in Table G2.4-7, there are exemptions for short-term noise exceedance, including those outlined in Table G2.4-8, which are based on the minutes per hour that the noise limit is exceeded. Based on the operations of LRVs moving on the tracks within the facility, the 5 dB adjustment is applied to the levels shown in Table G2.4-7.

Table G2.4-8 Washington State Exemptions for Short-Term Noise Exceedances

Minutes per Hour	Ln Value	Adjustment to Maximum Sound Level
15	L_{25}	+5 dB
5	$L_{8.3}$	+10 dB
1.5	$L_{1.5}$	+15 dB

Construction noise is exempt from the WAC noise limits, except at residential land uses during nighttime hours (10 p.m. to 7 a.m.). If construction is performed during nighttime hours, the contractor must still meet the WAC noise level requirements presented in Table G2.4-7 or obtain a noise variance from the governing jurisdiction.

Maximum permissible sound levels for haul trucks on public roadways are limited to 86 dBA for speeds of 35 mph or less and 90 dBA for speeds over 35 mph when measured at 50 feet (WAC 173-62).

Sounds created by backup alarms are exempt, except between 10 p.m. and 7 a.m. when “beep-beep” backup alarms are essentially prohibited by the WAC in urban areas and would be replaced with smart backup alarms, which automatically adjust the alarm level based on the background level or would be switched off and replaced with spotters. This condition is included because, just like noise from construction activities, noise from backup beepers would exceed the WAC nighttime criteria, even with the allowable exceedance, at large distances from the construction site.

5 AFFECTED ENVIRONMENT

The affected noise and vibration environment in the vicinity of the OMF South build alternatives and mainline track options to the Federal Way Downtown Station was investigated based on a review of current project and land use information, geographic information system (GIS) data, a windshield survey, and measurements conducted during November 2019. Land use in the OMF South study area includes a combination of residential, institutional, commercial, and industrial zones. Noise-sensitive and vibration-sensitive land uses in the study area were identified based on alignment drawings, aerial photographs, visual surveys, and land use information. Sensitive receptors located near the proposed alternatives include single-family and multi-family residences, hotels, and places of worship.

A summary of noise- and vibration-sensitive land uses adjacent to the OMF South build alternatives and mainline track is provided below, followed by descriptions of the existing noise and vibration conditions in the study area. There are no special buildings, such as recording studios, or highly vibration-sensitive buildings with specialized equipment known to be near any of the OMF South alternatives or the mainline track.

5.1 Noise and Vibration Sensitive Land Use

5.1.1 Preferred Alternative Site

The study area around the Preferred Alternative OMF South site and lead tracks includes a mix of commercial and noise-sensitive residential land uses. To the north of the site is a noise-sensitive residential community with a mix of single- and multi-family residences and the Russian-Ukrainian Seventh-Day Adventist Church. To the south is a mix of commercial uses with a few scattered noise-sensitive residences and the Restoration Life Church. To the west are commercial uses on both sides of SR 99 along with the KAC Baptist Church. I-5 is to the east.

5.1.2 South 344th Street Alternative Site

The study area around the South 344th Street Alternative OMF South site and lead tracks includes a mix of commercial, institutional, and noise-sensitive residential land uses. To the north of the site is a noise-sensitive residential community with a mix of single- and multi-family residences, the Christian Faith Center and associated school, the Russian-Ukrainian Seventh-Day Adventist Church, and the KAC Baptist Church. To the south are commercial uses. To the west are commercial uses on both sides of SR 99, and I-5 is to the east.

5.1.3 Midway Landfill Alternative

The land use around the Midway Landfill Alternative includes primarily commercial land uses to the west on both sides of SR 99, along with three religious facilities that are noise sensitive: the Great Commission Presbyterian Church, the New Jerusalem Haitian Baptist Church, and the Seattle Full Gospel Church. Noise-sensitive uses also include a mobile home park to the north and hotels and a single-family residential community to the south. To the east of the site is I-5.

5.1.4 Mainline Track

The noise-sensitive land uses adjacent to the mainline track design options and the test track between the Federal Way Downtown Station and the Preferred and South 344th Street alternatives are a mix of single- and multi-family residences, including the residences within the Belmor Mobile Home Park (Belmor). The land use around the mainline tail track alignments is commercial, with no noise-sensitive land uses.

5.2 Existing Noise Conditions

Existing noise sources in the project area include traffic on I-5, local roadway traffic, aircraft overflights, and local community activities. The existing ambient sound levels vary by location, depending on the proximity to I-5, and are generally typical of a suburban environment near a busy interstate. Existing ambient noise levels were characterized through direct measurements at selected sites in the area near the OMF South alternatives and mainline track during November 2019.

5.2.1 Noise Measurement Results

5.2.1.1 Preferred Alternative Site

Table G2.5-1 summarizes the results of the existing noise measurement program, and Figure G2.5-1 shows the locations of the three measurements for the Preferred Alternative. The results of the existing noise measurements were used to characterize the existing noise levels at all noise-sensitive locations near the Preferred Alternative.

Site F: Christian Faith Center West. The Ldn measured at this location was 67 dBA, and the peak hour Leq was 62 dBA. This location is representative of the residences to the north of the Preferred Alternative away from I-5 and the KAC Baptist Church. The ambient noise levels were dominated by local traffic and traffic on I-5.

Site G: Christian Faith Center East. The Ldn measured at this location was 72 dBA, and the peak hour Leq was 66 dBA. This location is representative of the residences to the north of the Preferred Alternative near I-5. The ambient noise levels were dominated by traffic on I-5.

Site H: 20th Avenue S and S 31st Place. The Ldn measured at this location was 73 dBA, and the peak hour Leq was 67 dBA. This location is representative of the residences to the south of the Preferred Alternative. The ambient noise levels were dominated by traffic on I-5.

Table G2.5-1 Summary of Existing Ambient Noise Measurements Results for Preferred Alternative

Site No.	Measurement Location Description	Start Date	Start Time	Meas. Duration (hours)	Noise Exposure (dBA) Ldn	Noise Exposure (dBA) 1 Hour Leq

5.2.1.3 Midway Landfill Alternative

Table G2.5-3 summarizes the results of the existing noise measurement program, and Figure G2.5-3 shows the locations of the three measurements for the Midway Landfill Alternative. The results of the existing noise measurements were used to characterize the existing noise levels at all noise-sensitive locations near the Midway Landfill.

Site A: Midway Landfill Southwest Corner. The Ldn measured at this location was 65 dBA, and the measured peak hour Leq was 62 dBA. This location is representative of the hotels and the residences to the south of the Midway Landfill away from I-5. The ambient noise levels were dominated by local traffic and traffic on I-5.

Site B: Midway Landfill Southeast Corner. The Ldn measured at this location was 71 dBA, and the measured peak hour Leq was 66 dBA. This location is representative of the residences to the south of the Midway Landfill near I-5. The ambient noise levels were dominated by traffic on I-5.

Site C: Midway Landfill North Side. The Ldn measured at this location was 67 dBA, and the measured peak hour Leq was 62 dBA. This location is representative of the residences to the north of the Midway Landfill and the religious facilities on SR 99. The ambient noise levels were dominated by local traffic and traffic on I-5.

5.2.1.4 Mainline Track Design Options

Table G2.5-4 summarizes the results of the existing noise measurement program, and Figures G2.5-1 and G2.5-2 show the locations of the two measurements for the mainline track design options. The results of the existing noise measurements were used to characterize the existing noise levels at all noise-sensitive locations near each option.

Site D: 11 The Dunes Court, Belmor. The Ldn measured at this location was 65 dBA, and the peak hour Leq was 59 dBA. This location is representative of the residences farther from I-5 near the mainline track design options. The ambient noise levels were dominated by local traffic and traffic on I-5.

Site E: 326 Oakland Hills Boulevard, Belmor. The Ldn measured at this location was 70 dBA, and the peak hour Leq was 65 dBA. This location is representative of the residences closer to I-5 near the mainline track design options. The ambient noise levels were dominated by traffic on I-5.

Table G2.5-4 Summary of Existing Ambient Noise Measurements Results for Mainline Track Options

Site No.	Measurement Location Description	Start Date	Start Time	Meas. Duration (hours)	Noise Exposure (dBA) Ldn	Noise Exposure (dBA) 1 Hour Leq
D	11 The Dunes Court, Belmor	11/19/19	12:00	24	65	59
E	326 Oakland Hills Boulevard, Belmor	11/19/19	12:00	24	70	65

5.3 Existing Vibration Conditions

Vibration-sensitive land uses for the project alternatives are the same as the noise-sensitive land uses described above. Existing vibration sources along the project alignments include auto, bus, and truck traffic on local streets. However, vibrations from street traffic are not generally perceptible at receivers in the study area unless streets have substantial bumps, potholes, or other uneven surfaces. Furthermore, the FTA vibration impact criteria are not ambient based; that is, future project vibrations are not compared with existing vibrations to assess impact. Therefore, the vibration measurements for the project focused on characterizing the soil conditions along the mainline track rather than on characterizing the existing vibration levels as described below.

One vibration propagation test site was selected for the 2019 measurements. The location of the site is shown on Figures G2.5-1 and G2.5-2, a site photograph is included in Attachment G2-1, and detailed propagation information is included in Attachment G2-3.

Site VP-A: Belmor. The vibration propagation measurement at this location was conducted in the vicinity of the mainline track design options in Belmor.

6 IMPACT ASSESSMENT

6.1 No-Build Alternative

Under the No-Build Alternative, noise impacts from the construction or operation of OMF South would not occur. However, for the purposes of this Final EIS the No-Build Alternative assumes that by the design year 2042, all planned Sound Transit 3 projects, including FWLE and TDLE, are built, along with the other public and private projects planned within the study area.

The noise and vibration effects of FWLE on sensitive receptors near the Midway Landfill Alternative have been addressed in the Federal Way Link Extension Final Environmental Impact Statement. FWLE constructed noise walls adjacent to the residential areas near the Midway Landfill to mitigate the anticipated noise impacts from that project. No vibration impacts from FWLE are anticipated in the area. The proposed alignment for the TDLE mainline track overlaps with the OMF South Preferred and South 344th Street alternatives. If TDLE is constructed as proposed, the mainline track associated with these alternatives would be built later in time. The noise and vibration effects of TDLE and Federal Way's City Center Access Project on sensitive receptors within the study area for the Preferred and South 344th Street alternatives are discussed in Section 7, Cumulative Impacts. Noise and vibration impacts from TDLE will be further detailed in the TDLE Draft EIS, expected to be published in mid-2024.

In addition, there would likely be increases in highway and local roadway noise due to increased traffic volumes as a result of anticipated population and job growth in the study areas.

6.2 Build Alternatives

Detailed noise and vibration impact assessments were performed based on the criteria discussed in Section 4 and the prediction methodology described in Section 3. The assessment results are presented in this section. The FTA guidance manual is the primary source for the noise methodology. During final design, all impacts would be reevaluated to verify impact levels and inform the mitigation design.

The noise and vibration assessments included the following steps:

- Noise- and vibration-sensitive land uses were identified using aerial photography, GIS data, and field surveys. See Section 5.1.
- Existing noise levels along the corridor were measured at sensitive receptors. See Section 5.2.
- Vibration-propagation characteristics of the soil along the corridor were measured at a representative sensitive receptor. See Section 5.3.
- Project noise and vibration levels from transit operations were predicted using project drawings and information on speeds, headways, track type, vehicle type, crossover locations, and facility operations.
- The noise impact from transit operations, facility operations, and test track operations was assessed by comparing the project noise with the existing noise (not the No-Build Alternative noise) using the FTA noise impact criteria. See Figure G2.4-1.
- The vibration impact from transit operations was assessed by comparing the project vibration levels with the FTA vibration impact criteria in Figure G2.4-3.

- Project noise levels were also compared with the WAC noise criteria for exceedances.
- Mitigation was recommended at locations where project noise or vibration levels exceed the impact criteria.
- Wheel squeal for tight radius curves is not included in the noise model because Sound Transit has committed to reducing any potential wheel squeal by installing wayside lubricators on all curves in noise-sensitive areas with a radius of less than 600 feet and by preparing all curves for wayside lubricators that have a radius of between 600 and 1,000 feet, including those in the OMF. There are numerous tight radius curves within the sites for all three OMF build alternatives that would also be prepared for wayside lubricators.

6.2.1 Preferred Alternative Site

Comparisons of the existing and future noise levels are presented in Table G2.6-1 and Table G2.6-2 for the Preferred Alternative site. Table G2.6-3 includes the results for FTA Category 2 (residential) receptors with both daytime and nighttime sensitivity to noise, and Table G2.6-4 includes the results for FTA Category 3 (institutional) receptors with daytime and evening use. There were no FTA Category 1 (high sensitivity) receptors in the study area for this alternative. In addition to the distances to the nearest track, the tables include the existing noise levels, the projected noise levels from facility operations, and the FTA noise impact criteria. Based on a comparison of the predicted project noise levels with the impact criteria, the tables also include an inventory of the moderate and severe noise impacts for the Preferred Alternative site.

Table G2.6-1 Summary of FTA Category 2 Noise Impacts for the Preferred Alternative Site

Location	Side of OMF	Distance to Nearest Proposed Track (feet)	Existing Noise Level (Ldn, dBA)	Project Noise Level (Ldn, dBA)	Moderate Noise Criteria	Severe Noise Criteria	# of Moderate Impacts	# of Severe Impacts
S 336th Street	North	176	67	48	62	68	0	0
18th Place S	South	933	73	36	65	71	0	0
Total:							**0**	**0**

Table G2.6-2 Summary of FTA Category 3 Noise Impacts for the Preferred Alternative Site

Location	Side of OMF	Distance to Nearest Proposed Track (feet)	Existing Noise Level (Ldn, dBA)	Project Noise Level (Ldn, dBA)	Moderate Noise Criteria	Severe Noise Criteria	# of Moderate Impacts	# of Severe Impacts
Russian-Ukrainian Seventh-Day Adventist Church	North	180	62	<20	64	70	0	0
KAC Baptist Church	West	295	62	<20	64	70	0	0
Restoration Life Church	South	857	67	<20	67	72	0	0
Total:							**0**	**0**

Table G2.6-3 shows a comparison of the maximum noise levels from facility operations with the WAC thresholds for residential land uses at night. Because the majority of the activity at the facility would occur at night, and commercial and industrial uses typically do not have activity at night, only the residential night threshold is assessed.

Table G2.6-3 Summary of WAC Nighttime Noise Exceedances for the Preferred Alternative Site

Location	Side of OMF	Distance to Nearest Proposed Track (feet)	Project Noise Level (Leq, dBA)	Noise Level for Impact	# of Exceedances
S 336th Street	North	180	42	55	0
18th Place S	South	933	30	55	0
Total:					**0**

There are no FTA noise impacts or WAC exceedances for the Preferred Alternative site.

6.2.2 South 344th Street Alternative Site

Comparisons of the existing and future noise levels are presented in Table G2.6-4 and Table G2.6-5 for the South 344th Street Alternative site. Table G2.6-4 includes the results for FTA Category 2 (residential) receptors with both daytime and nighttime sensitivity to noise, and Table G2.6-5 includes the results for FTA Category 3 (institutional) receptors with daytime and evening use. There were no FTA Category 1 (high sensitivity) receptors in the study area for this alternative. In addition to the distances to the nearest track, the tables include the existing noise levels, the projected noise levels from facility operations, and the FTA noise impact criteria. Based on a comparison of the predicted project noise levels with the impact criteria, the tables also include an inventory of the moderate and severe noise impacts for the South 344th Street Alternative site.

Table G2.6-4 Summary of FTA Category 2 Noise Impacts for the South 344th Street Alternative Site

Location	Side of OMF	Distance to Nearest Proposed Track (feet)	Existing Noise Level (Ldn, dBA)	Project Noise Level (Ldn, dBA)	Moderate Noise Criteria	Severe Noise Criteria	# of Moderate Impacts	# of Severe Impacts
S 336th Street	North	1210	67	40	62	68	0	0
S 340th Street	West	510	67	44	62	68	0	0
Total:							**0**	**0**

Table G2.6-5 Summary of FTA Category 3 Noise Impacts for the South 344th Street Alternative Site

Location	Side of OMF	Distance to Nearest Proposed Track (feet)	Existing Noise Level (Ldn, dBA)	Project Noise Level (Ldn, dBA)	Moderate Noise Criteria	Severe Noise Criteria	# of Moderate Impacts	# of Severe Impacts
Russian-Ukrainian Seventh-Day Adventist Church	North	1130	62	<20	64	70	0	0
KAC Baptist Church	West	970	62	<20	64	70	0	0
Christian Faith Center	West	240	62	<20	64	70	0	0
Restoration Life Church	West	1060	67	<20	67	73	0	0
Total:							**0**	**0**

Table G2.6-6 shows a comparison of the maximum noise levels from facility operations with the WAC thresholds for residential land uses at night. Because the majority of the activity at the facility would occur at night, and commercial and industrial uses typically do not have activity at night, only the residential night threshold is assessed.

Table G2.6-6 Summary of WAC Nighttime Noise Exceedances for the South 344th Street Alternative Site

Location	Side of OMF	Distance to Nearest Proposed Track (feet)	Project Noise Level (Leq, dBA)	Noise Level for Impact	# of Exceedances
S 336th Street	North	1210	34	55	0
S 340th Street	West	510	41	55	0
Total:					**0**

There are no FTA noise impacts or WAC exceedances for the South 344th Street Alternative site.

6.2.3 Midway Landfill Alternative

Comparisons of the existing and future noise levels with the Midway Landfill Alternative are presented in Table G2.6-7 and Table G2.6-8. Table G2.6-7 includes the results for FTA Category 2 (residential) receptors with both daytime and nighttime sensitivity to noise, and Table G2.6-8 includes the results for FTA Category 3 (institutional) receptors with daytime and evening use. There were no FTA Category 1 (high sensitivity) receptors in the study area for this alternative. In addition to the distances to the nearest track, the tables include the existing noise levels, the projected noise levels from facility operations, and the FTA noise impact criteria. Based on a comparison of the predicted project noise levels with the impact criteria, the tables also include an inventory of the moderate and severe noise impacts for the Midway Landfill Alternative.

Table G2.6-7 Summary of FTA Category 2 Noise Impacts for the Midway Landfill Alternative

Location	Side of OMF	Distance to Nearest Track (feet)	Existing Noise Level (Ldn, dBA)	Project Noise Level (Ldn, dBA)	Moderate Noise Criteria	Severe Noise Criteria	# of Moderate Impacts	# of Severe Impacts
Midway Mobile Mansions	North	490	67	45	62	67	0	0
SR 99 Motels	West	230	65	40	61	66	0	0
S 252nd Street	South	270	71	40	65	70	0	0
Total:							**0**	**0**

Table G2.6-8 Summary of FTA Category 3 Noise Impacts for the Midway Landfill Alternative

Location	Side of OMF	Distance to Nearest Track (feet)	Existing Noise Level (Ldn, dBA)	Project Noise Level (Ldn, dBA)	Moderate Noise Criteria	Severe Noise Criteria	# of Moderate Impacts	# of Severe Impacts
New Jerusalem Haitian Baptist Church	West	640	62	<20	64	69	0	0
Seattle Full Gospel Church	West	860	62	<20	64	69	0	0
Great Commission Presbyterian Church	West	780	62	<20	64	69	0	0
Total:							**0**	**0**

Table G2.6-9 shows a comparison of the maximum noise levels from facility operations with the WAC thresholds for residential land uses at night. Because the majority of the activity at the facility would occur at night, and commercial and industrial uses typically do not have activity at night, only the residential night threshold is assessed.

Table G2.6-9 Summary of WAC Nighttime Noise Exceedances for the Midway Landfill Alternative

Location	Side of OMF	Distance to Nearest Track (feet)	Project Noise Level (Leq, dBA)	Noise Level for Impact	# of Exceedances
Midway Mobile Mansions	North	490	41	55	0
SR 99 Motels	West	230	41	55	0
S 252nd Street	South	270	40	55	0
Total:					**0**

There are no FTA noise impacts or WAC exceedances for the Midway Landfill Alternative.

6.3 Preferred and South 344th Street Alternatives Mainline and Test Track Noise

For the Preferred and South 344th Street alternatives mainline track design options and the test track, comparisons of the existing and future noise levels are presented in Table G2.6-10 and Table G2.6-11. Table G2.6-10 includes the results for FTA Category 2 (residential) receptors with both daytime and nighttime sensitivity to noise for the 40 mph Alignment, and Table G2.6-11 includes the results for FTA Category 2 receptors for the 55 mph Design Option. There are no FTA Category 1 (high sensitivity) or Category 3 (industrial) land uses near the mainline track design options.

In addition to the distances to the nearest track, Table G2.6-10 and Table G2.6-11 include the existing noise levels, the projected noise levels from LRV operations, and the FTA noise impact criteria. Based on a comparison of the predicted project noise levels with the impact criteria, the table also includes an inventory of the moderate and severe noise impacts for the mainline tracks.

There would be no FTA noise impacts for the 40 mph Alignment and four FTA moderate impacts for the 55 mph Design Option. The noise impacts are at single-family residences and are due to the proximity to the proposed tracks. The noise impact locations are shown in Figure G2.6-1 for the 55 mph Design Option, and the projected noise impacts are described below.

Table G2.6-10 Summary of FTA Category 2 Noise Impacts for the 40 mph Alignment Mainline Track

Location	Side of Track	Distance to Nearest Proposed Track (feet)	Existing Noise Level (Ldn, dBA)	Project Noise Level (Ldn, dBA)	Moderate Noise Criteria	Severe Noise Criteria	# of Moderate Impacts	# of Severe Impacts
S 324th Street to Burning Tree Boulevard	SB[1]	80	70	62	64	69	0	0
Burning Tree Boulevard to S 330th Street	SB	111	70	56	64	69	0	0
S 330th Street to S 333rd Street	SB	81	72	58	65	71	0	0
S 333rd Street to S 336th Street	SB	197	72	64(58)[2]	65	71	0 (0)[2]	0 (0)[2]
Total:							**0 (0)[2]**	**0 (0)[2]**

Note:

(1) SB = southbound.

(2) The Preferred Alternative is shown first, followed by the South 344th Street Alternative in parenthesis. The lead tracks and crossovers from the OMF would be further south for the South 344th Street Alternative in comparison to the Preferred Alternative.

Table G2.6-11 Summary of FTA Category 2 Noise Impacts: 55 mph Design Option Mainline Track

Location	Side of Track	Distance to Nearest Proposed Track (feet)	Existing Noise Level (Ldn, dBA)	Project Noise Level (Ldn, dBA)	Moderate Noise Criteria	Severe Noise Criteria	# of Moderate Impacts	# of Severe Impacts
S 324th Street to Burning Tree Boulevard	NB[1]	76	65	61	64	69	2	0
S 324th Street to Burning Tree Boulevard	SB[1]	57	65	64	61	66	2	0
Burning Tree Boulevard to S 330th Street	SB	85	70	57	64	69	0	0
S 330th Street to S 333rd Street	SB	81	72	58	65	71	0	0
S 333rd Street to S 336th Street	SB	197	72	64 (58)[2]	65	71	0 (0)[2]	0 (0)[2]
Total:							**4 (4)[2]**	**0 (0)[2]**

Note:

(1) NB = northbound, SB = southbound.

(2) The Preferred Alternative is shown first, followed by the South 344th Street Alternative in parenthesis. The lead tracks and crossovers from the OMF would be further south for the South 344th Street Alternative in comparison to the Preferred Alternative.

S 324th Street to Burning Tree Boulevard (NB): Two single-family residences between S 324th Street and Burning Tree Boulevard on the northbound side of the mainline track are projected to have moderate noise impacts. These impacts are due to the proximity of the tracks.

S 324th Street to Burning Tree Boulevard (SB): Two single-family residences between S 324th Street and Burning Tree Boulevard on the southbound side of the mainline track are projected to have moderate noise impacts. These impacts are due to the proximity of the tracks.

OMF South

6.3.1 Traffic Noise

Construction of either mainline alignment would modify a portion of an existing berm and remove noise walls adjacent to I-5 that screen residences from traffic noise between S 320th Street and S 336th Street. The berm and noise walls were anticipated to be removed by the City of Federal Way's City Center Access Project, which would construct a new interchange with roundabouts and a new bridge over I-5 at S 324th Street. However, the City Center Access Project is now anticipated to be constructed after OMF South. As a result, Sound Transit would modify the existing berm and remove approximately 1,390 linear feet of noise walls as part of the OMF South project.

While the retained fill structure to support the mainline would serve as a barrier to traffic noise from I-5, the modification of the existing berm and noise walls is anticipated to result in traffic noise impacts for about one to three residences (Sound Transit 2023a). In final design, Sound Transit would conduct additional noise analysis in coordination with Federal Way and WSDOT to verify the findings of the noise analysis, determine whether replacement of noise walls would be necessary, and ensure that the location of any new noise walls would be consistent with the plans for the City Center Access Project.

Figure G2.6-2, Proposed Modifications to Highway Noise Walls, shows the location of the existing noise wall and berm and the areas that would be modified to accommodate the construction of the mainline tracks for OMF South under the Preferred or South 344th Street alternatives.

6.4 Vibration

Because there are no highly vibration-sensitive land uses located near the OMF South alternatives, and due to the very low train speeds within the facility, vibration levels would be well below the impact thresholds for sensitive receptors near the three site alternatives and have not been assessed. However, vibration has been assessed for the LRV operations on the mainline and test tracks between the Preferred and the South 344th Street alternatives and the Federal Way Downtown Station.

This section describes the vibration impacts for the LRV operations on the mainline track design options. Table G2.6-12 includes the results for FTA Category 2 (residential) receptors with both daytime and nighttime sensitivity to vibration for the 40 mph Alignment, and Table G2.6-13 includes the results for FTA Category 2 receptors for the 55 mph Design Option. There are no FTA Category 1 (high sensitivity) or Category 3 (industrial) land uses near the mainline track design options.

The results include a tabulation of location information for each sensitive receptor group, the projections of future vibration levels, the impact criteria, and whether there will be vibration impacts. The tables also show the total number of vibration impacts for each location. There are no vibration impacts projected for either mainline track design option.

Table G2.6-12 Summary of FTA Category 2 Vibration Impacts for the 40 mph Alignment Mainline Track

Total:					**0**

Note: NB = northbound, SB = southbound.

6.5 Construction Noise

Elevated noise levels from construction activities are, to a degree, unavoidable for this type of project. For most construction equipment, diesel engines are typically the dominant noise source. For other activities, such as impact pile driving and jackhammering, noise generated by the actual process dominates. Short-term noise during construction of the project can be intrusive to residents near the construction sites. Most of the construction will consist of site preparation and laying new tracks and would primarily occur during daytime hours within local noise ordinance requirements for a waiver. At some locations, more extensive work will occur, such as pile driving for elevated structures and retaining walls.

Table G2.3-1 in Section 3 lists noise levels of typical construction equipment from the FTA guidance manual in terms of the maximum levels at 50 feet. Construction noise predictions at noise-sensitive locations depend on the amount of noise during each construction phase, the duration of the noise, and the distance from the construction activities to the sensitive receptor. Table G2.6-14 provides an example of a construction noise projection for typical at-grade track construction. Construction for other project features, such as buildings, would have similar results. Using these assumptions, an 8-hour Leq of 88 dBA would be projected at a distance of 50 feet from the construction site.

Using the criteria in Section 4.3 and the example for at-grade construction in Table G2.6-14, screening distances for at-grade track construction noise impact can be determined. For residential land use, the potential for short-term at-grade track construction noise impact could extend to approximately 120 feet from the corridor or OMF South site; however, if nighttime construction is conducted (when sensitivity to noise is higher and the criteria for impact are lower), the potential for short-term noise impact from at-grade construction could extend to approximately 380 feet from the corridor. For elevated structure construction, the distance for noise impact during the daytime could be up to 250 feet for impact pile driving, assuming a usage factor of 20 percent during the day. If alternative methods of piling are used, the distance to impact could be less. When a specific piling method has been determined, a screening distance could be calculated.

Based on the distances above, there would be sensitive receptors within the screening distances for all three OMF South alternatives, including the mainline track design options. Noise impacts perceived by residents and other sensitive receptors would vary depending on the proximity of the construction activity, the type of equipment being used, the time of day, and the overall duration of construction. While the noise levels would be similar for construction of any of the build alternatives, the Hybrid and Full Excavation design options for the Midway Landfill Alternative would have a greater impact due to the extended period of time needed for site preparation work.

Table G2.6-14 Typical Construction Scenario, At-Grade Track

Equipment Type	Typical Noise Level at 50 Feet (dBA)	Equipment Utilization Factor (%)	Leq (dBA)
Grader	85	50	82
Backhoe	80	40	76
Compactor	82	20	75
Loader	85	20	78
Roller	74	20	67
Truck	88	40	84
Crane, mobile	83	20	76
Total 8-hour workday Leq at 50 feet:			**88**

6.6 Construction Vibration

Unlike typical LRV operations, there is the potential for damage to nearby structures at close distances due to construction vibration from activities, such as pile driving, hoe rams, vibratory compaction, and loaded trucks. Most limits on construction vibration are based on reducing the potential for damage to nearby structures. Although construction vibrations are only temporary, it is still reasonable to assess the potential for human annoyance and damage.

As a conservative approach, the nonengineered timber and masonry construction category (Category III) has been used to assess the potential for construction vibration impacts. A vibration criterion of 94 VdB has been used to assess potential damage impact, and 72 VdB has been used to assess potential vibration annoyance from construction activities. Vibration source levels at 25 feet and the distances to potential residential annoyance and potential damage are shown in Table G2.6-15. With the exception of impact pile driving, the potential for damage is limited to within 25 feet of construction activities. For impact pile driving, the distance for the potential for damage is up to 55 feet. There are no sensitive receptors within 25 feet of the OMF South site alternatives, but there are several within 55 feet of the mainline track design options in Belmor. However, any potential for impacts would depend on the piling method chosen.

Because the exact location of construction equipment is important in projecting vibration levels, a more detailed assessment of potential vibration damage will be performed during final design when more accurate equipment locations are known.

Table G2.6-15 Summary of Potential Construction Vibration Impacts

Equipment Type	Typical Vibration Level at 25 Feet (VdB)	Distance for Potential Damage (feet)	Distance for Potential Annoyance (feet)
Impact pile driving	104	55	290
Push piling	84	25	125
Hoe ram	87	15	80
Caisson drilling	87	15	80
Loaded trucks	86	15	75
Clam shovel	94	25	135
Vibratory roller	94	25	135

7 CUMULATIVE IMPACTS

Cumulative impacts for the OMF South project would be associated with TDLE and Federal Way's proposed City Center Access Project for the Preferred and South 344th Street alternatives. Please see Figure G2.7-1, Cumulative Transit and Traffic Noise Impacts. There would be no cumulative noise impacts associated with the Midway Landfill Alternative.

If TDLE is constructed, approximately 144 LRVs would be needed and stored at OMF South. With the additional vehicles, there would be additional operations within the facility, including additional LRV movements into and out of the facility in the morning and evening, respectively. Additionally, for the Preferred and South 344th Street alternatives, the LRVs leaving and entering would be split between the northern and southern tracks leading to the mainline tracks. The additional LRVs from TDLE operating from within the OMF South alternative sites would increase some noise levels, but they would not be loud enough to cause FTA noise impacts or WAC exceedances.

As described previously, the mainline tracks connecting the Preferred and South 344th Street alternatives would become the operational track for TDLE. With TDLE, additional trains would use the mainline tracks, and they would operate at higher speeds. As a result, the operation of TDLE is anticipated to cause additional noise impacts to residences along the mainline tracks in Belmor from either the 40 mph Alignment or the 55 mph Design Option. Impacts would also occur where the mainline curves south of S 324th Street and near the mainline north of S 336th Street. There would be no cumulative noise impacts from TDLE for the Midway Landfill Alternative because the mainline tracks adjacent to the site would already be built as part of FWLE and operating as revenue-generating tracks.

There would be no vibration impacts associated with OMF South. With the inclusion of the TDLE project, there would be an increase in vibration levels due to the higher speed of the trains, but no cumulative vibration impacts are anticipated. With the Midway Landfill Alternative, there would be no cumulative vibration impacts from the FWLE project.

Further details regarding TDLE noise and vibration impacts and mitigation will be included in the TDLE Draft EIS, which is expected to be published in mid-2024. The Draft EIS will include recommended mitigation measures, such as noise barriers, for any noise impacts on sensitive receptors near the mainline tracks, which would address the cumulative effects of TDLE for the Preferred or South 344th Street alternatives. To improve efficiency and eliminate the impacts of two construction activities in the same location, the OMF South project is anticipated to construct noise mitigation required for TDLE if the Preferred Alternative or South 344th Street Alternative is selected as the project to be built.

The City Center Access Project, together with OMF South and TDLE, could result in cumulative noise impacts to a small number of receptors south of S 324th Street. The City Center Access Project proposes to extend S 324th Street across I-5 to the east, which may increase motor vehicle traffic noise that would require mitigation.

FIGURE G2.7-1
Cumulative Transit and Traffic Noise Impacts

8 MITIGATION

8.1 Operational Noise

The Sound Transit Link Light Rail Noise and Vibration Policy (Sound Transit 2023b) sets source mitigation as the preferred method of mitigation, followed by path mitigation, such as noise barriers, and then receiver mitigation last, which would include sound insulation of properties. There are several methods of noise mitigation available, including:

- **Noise Barriers:** Installation of noise barriers beside the tracks is commonly used to reduce noise from surface transportation sources. Depending on the height and location relative to the tracks, noise barriers can achieve between 5 and 15 dB of noise reduction. The primary requirements for an effective noise barrier are that (1) the barrier must be high enough and long enough to break the line of sight between the sound source and the receiver, (2) the barrier must be of an impervious material with a minimum surface density of 4 pounds per square foot, and (3) the barrier must not have any gaps or holes between the panels or at the bottom. Because many materials meet these requirements, the selection of materials for noise barriers is usually dictated by aesthetics, durability, cost, and maintenance considerations. Noise barriers for transit projects typically range from 8 to 12 feet in height along at-grade track and can be as low 4 feet in height on elevated structures.
- **Building Sound Insulation:** Although typically used as a last resort, sound insulation may be necessary when noise barriers are not feasible or desirable and for buildings where indoor sensitivity is of most concern. Substantial improvements in building sound insulation (on the order of 5 to 10 dBA) can often be achieved by adding an extra layer of glazing to the windows, by sealing holes in exterior surfaces that act as sound leaks, and by providing forced ventilation and air-conditioning so that windows do not need to be opened.

For the Preferred and South 344th Street alternatives, the mainline 40 mph Alignment curves north of S 324th Street and from S 324th Street to Oakland Hills Boulevard would have a radius between 600 and 1,000 feet and would be prepared for wayside lubricators.

Noise barriers are proposed for mitigation along the elevated 55 mph Design Option mainline track for the Preferred and South 344th Street alternatives. The approximate locations and lengths of the noise barriers are shown in Table G2.8-1 and shown in Figure G2.8-1. The final height and length of the barriers would be determined based on additional analysis of potential noise impacts during final design. However, typical noise barriers are 4 feet in height on elevated structures. Assuming 4-foot barriers on the elevated structure at the locations described below, the barriers would provide approximately 8 dB of noise reduction (with 1 and 3 dB of reduction required to eliminate impacts, respectively), and there would be no residual impacts after mitigation. No mitigation would be necessary for the Midway Landfill Alternative.

The noise mitigation for the cumulative effects of TDLE on sensitive receptors near the mainline and the Preferred or South 344th Street alternatives could include one or more of a combination of the methods described above. This will be further detailed in the TDLE Draft EIS, which is expected to be published in mid-2024.

Table G2.8-1 Summary of Potential Noise Barrier Locations

Project Alternative	Approximate Location	Noise Barrier Length (feet)
55 mph Design Option	Northbound side from south of park-and-ride to south of Burning Tree Boulevard	360
55 mph Design Option	Southbound side from south of park-and-ride to south of Burning Tree Boulevard	325

8.1.1 Traffic Noise

Mitigation for traffic noise impacts caused by a project is designed to ensure that, whenever possible, there would be no residences in the study area with project-related traffic noise levels at or above the WSDOT NAC of 66 dBA. In circumstances where existing WSDOT noise barriers (such as walls or berms constructed for the purpose of traffic noise abatement) would be removed or altered by a project, mitigation would be designed to ensure that, whenever possible, there would be no residences with traffic noise levels above the predicted 2042 No-Build levels.

For the Preferred and South 344th Street alternatives, Sound Transit would provide traffic noise mitigation measures where traffic noise levels are predicted to be above the 2042 No-Build levels from removal of the existing WSDOT berm and noise wall. Mitigation would be designed to maintain 2042 No-Build noise levels and could include replacement of noise walls and berms. Sound Transit would conduct additional noise analysis during final design in coordination with WSDOT to confirm whether noise mitigation is needed.

8.2 Operational Vibration

No operational vibration impacts are projected to occur; therefore, no vibration mitigation is required.

8.3 Construction

Construction activities would be carried out in compliance with Sound Transit specifications and applicable local noise regulations. Construction noise is exempt from the WAC noise limits, except at residential land uses during nighttime hours (10 p.m. to 7 a.m.). If construction is performed during nighttime hours, the contractor must meet the WAC noise level requirements or obtain a noise variance from the governing jurisdiction. Specific construction noise and vibration mitigation measures would be developed during the final design phase of the project when more detailed construction information is available. The following measures could be applied as needed to minimize temporary construction noise and vibration impacts:

- Avoiding nighttime construction in residential neighborhoods when possible
- Locating stationary construction equipment as far as possible from noise-sensitive sites
- Constructing noise barriers, such as temporary walls or piles of excavated material, between noisy activities and noise-sensitive receivers
- Routing construction-related truck traffic to roadways that will cause the least disturbance to residents
- Using alternative construction methods to minimize the use of impact and vibratory equipment (e.g., pile drivers and compactors). If pile driving is necessary, it would be limited to daytime hours

The primary means of mitigating noise and vibration from construction activities is to require the contractors to prepare a detailed Noise and Vibration Control Plan. A noise control engineer or acoustician would work with the contractor to prepare a Noise and Vibration Control Plan in conjunction with the contractor’s specific equipment and methods of construction. Key elements of a plan could include the following:

- Contractor’s specific equipment types
- Schedule (dates and times of day) and methods of construction
- Maximum noise limits for each piece of equipment with certification testing
- Prohibitions on certain types of equipment and processes during the night or day time hours per local agency coordination and approved variances
- Identification of specific sensitive sites where near construction sites
- Methods for projecting construction noise levels
- Implementation of noise and vibration control measures where appropriate
- Methods for responding to community complaints in compliance with Sound Transit Outreach requirements

Federal Transit Administration

SOUNDTRANSIT

June 2024

Summary

This technical report addresses ecosystem components that may be affected by the Sound Transit Operations and Maintenance Facility South (OMF South) Project. The ecosystem components addressed in this report are aquatic species and habitat, vegetation, wildlife and wildlife habitat, and wetlands. The report describes the affected environment and the expected temporary construction impacts and permanent long-term operational impacts of the proposed alternatives, including the No-Build Alternative, on these resources. It also identifies measures intended to avoid and minimize impacts and potential compensatory mitigation for unavoidable impacts.

This technical report was prepared to meet the requirements of the National Environmental Policy Act (NEPA) and the Washington State Environmental Policy Act (SEPA) to support the OMF South NEPA/SEPA Final Environmental Impact Statement (Final EIS). The technical report provides information that would typically be addressed in a biological assessment or other document that demonstrates compliance with the requirements of Section 7(c) of the Endangered Species Act (ESA). Further, this report addresses potential effects on Essential Fish Habitat, consistent with the requirements for federal action agencies under the Magnuson-Stevens Fishery Conservation and Management Act.

Under any of the build alternatives, direct long-term impacts on ecosystem resources would occur where permanent features such as project facilities overlap features such as streams, stream buffers, native or structurally complex vegetation, wetlands, or wetland buffers. Temporary, construction-related impacts would occur where such features are affected by clearing and ground disturbing work but are revegetated following construction.

Aquatic Species and Habitats

The study area includes two streams: East Fork Hylebos Creek Tributary 0016A and West Fork Hylebos Creek Tributary 0014C (referred to as East Fork Hylebos Tributary and West Fork Hylebos Tributary, respectively, in this Final EIS). Both are tributaries to Hylebos Creek, an independent tributary that discharges to the Hylebos Waterway along the eastern shore of Puget Sound's Commencement Bay in Tacoma. A third stream (North Fork McSorley Creek) would receive treated stormwater runoff from the Midway Landfill Alternative but would otherwise not be directly affected by project construction or operation. All three streams are classified as Type F streams, meaning they have the potential to support fish.

Three ESA-listed fish species could potentially occur in the study area. These are Puget Sound Chinook salmon, Puget Sound steelhead, and bull trout, all of which are federally listed as threatened. Numerous barriers to fish passage, combined with small stream sizes and intermittent flow regimes, prevent any of these species from entering stream reaches in the study area. None of the streams in the study area include any proposed or designated critical habitat for ESA-listed species.

Direct long-term impacts on aquatic resources would occur where permanent features such as project facilities permanently alter in-stream habitat (including habitat accessibility) or riparian functions. Additional impacts may occur where surface waters receive stormwater runoff from impervious surfaces created or replaced by project construction. Potential construction-related impacts include temporary disturbance of riparian vegetation and an elevated risk of delivering sediment or contaminants, such as fuel and hydraulic fluids to streams during construction.

Sound Transit has committed to minimizing the need to place existing streams in new culverts and has designed the OMF South alternatives to avoid new stream piping whenever possible. However, two to three culverts may need to be replaced as part of the Preferred Alternative, and these replaced culverts, which may be longer, would be made fish passable. If any culverts on potentially fish-bearing streams are replaced, the replacement structures would be designed and installed in accordance with WDFW's Water Crossing Design Guidelines (Barnard et al. 2013). In the interim design, the replacement structure for West Fork Hylebos Tributary would have a substantially larger hydraulic opening than the existing culverts at that site. The installation of an appropriately sized structure would help restore hydrological capacity, allowing flood flows, sediment and organic debris to pass through and (if access is restored in the future) providing unhindered fish passage beneath the roadway.

Under the Preferred Alternative (referred to as the South 336th Street Alternative in the 2021 Draft EIS) or the South 344th Street Alternative, construction of the OMF facility and associated elevated mainline tracks would necessitate the realignment of the stream channel for East Fork Hylebos Tributary. The interim design includes meanders and other features that would increase the length of the stream channel by approximately 130 linear feet, enhancing the availability and diversity of aquatic habitats. Large woody debris would be placed in and near the stream channel to provide additional habitat complexity. The relocated channel would be designed to maintain flows and water quality conditions.

Along an approximately 380-foot-long segment of the relocated stream channel, the width of the area available to support riparian functions would be expanded under these alternatives. Under current conditions, the vegetated riparian zone in that area is confined to an approximately 80-foot-wide strip. Upon project completion, the width of the area between the OMF site and the mainline tracks would be approximately 200 feet.

Although relocating and realigning the stream channel would have some beneficial effects, changing the physical characteristics of the stream could affect its hydrology and downstream sediment regimes. In addition, the presence of the OMF site to the west and the mainline tracks to the east would further reduce the width of the already limited area available to support riparian functions. In general, other than the 380 feet of expanded riparian buffer along the relocated channel, both the Preferred and the South 344th Street alternatives would have a net reduction in riparian habitat width. Also, the presence of support columns for the elevated mainline tracks may constrain options for natural or human-created modifications to channel configuration in the future. Approximately 1,650 linear feet of East Fork Hylebos Tributary would be reconfigured under the Preferred Alternative, compared to approximately 1,500 linear feet under the South 344th Street Alternative.

Under the Preferred Alternative, East Fork Hylebos Tributary at the downstream end of the study area would be conveyed under the 21st Avenue S extension and S 344th Street in a new structure that would replace the existing, approximately 315-foot-long culvert. Under the South 344th Street Alternative, this culvert would be replaced with an approximately equal daylighted length of surface-flowing stream. Daylighting would allow increased interaction between the stream and associated riparian vegetation, resulting in beneficial effects associated with restoring natural processes such as organic input and flow attenuation.

Emergency vehicle access to the mainline tracks would be needed near the location of the stream segment that would be daylighted under the South 344th Street Alternative. One of the options under consideration may require approximately 60 feet of channel that is currently culverted (and that would otherwise be daylighted, as described above) to be placed in a new culvert. It may be possible to eliminate the need for a culvert through detailed design of the access and of the stream meanders. The design of the emergency vehicle access would need to be coordinated and approved by Sound Transit, WSDOT, and the city of Federal Way.

Construction and operation of the Preferred Alternative would affect aquatic and riparian habitats associated with West Fork Hylebos Tributary where it flows through a wetland and associated in-line stormwater detention facility south of S 336th Street. The stream lacks a defined bed and bank in the wetland. Potential project-related impacts could include reduced riparian function and alterations to peak flows.

The Midway Landfill Alternative would not be expected to affect aquatic resources because it would not include any construction activities within 200 feet of a surface-flowing stream.

Vegetation, Wildlife, and Wildlife Habitat

Much of the study area is dominated by urban development, including industrial, institutional, commercial, and residential areas. These areas support plant and animal species adapted to disturbed urban areas. However, patches of less-developed habitats occur along the Hylebos Creek tributaries in Federal Way and at the Midway Landfill in Kent.

Analysts identified and delineated 10 vegetation cover types in the study area and evaluated their relative habitat value. Relative habitat value is based on habitat structure, scarcity in the study area, disturbance types and frequency, and time required for ecosystem functions to recover following clearing and post-construction revegetation.

No plant or wildlife species that are listed or proposed for listing under the ESA are known or expected to use habitats in the study area. Patches of mature forest, a state priority habitat, are found in riparian areas along East Fork Hylebos Tributary within the study area.

Impacts on terrestrial resources would occur where project construction converts vegetation or other wildlife habitat features to project facilities. Clearing for project construction would also increase the risk of contributing to the spread of noxious or invasive weed species. Noise, light, and human activity associated with construction and operation of OMF South may also have short- and long-term impacts on wildlife.

The extent of the Preferred Alternative’s effects on native and complex habitats would be greater than any of the other alternatives. Compared to the other project alternatives, the Midway Landfill Alternative would have minimal effects on existing native or complex habitats and a lower risk of contributing to the establishment and spread of noxious weeds and invasive plants.

Wetlands

Sound Transit identified a total of 23 wetlands in the study area. Biologists performed formal delineations of wetland boundaries in legally accessible areas associated with the Hylebos Creek tributaries, which included most wetlands in the study area. Agencies, Tribes, and the public expressed a high level of concern about potential impacts on ecosystem resources in these areas. While formal delineations are not typically required at this stage of the environmental review process, Sound Transit determined that detailed information collected early in the process would help the design team avoid or minimize impacts on wetlands. Other wetlands were mapped and characterized during site reconnaissance visits.

The Preferred Alternative would have the greatest degree of permanent impacts on wetlands and wetland buffers and of temporary (construction-related) impacts on wetlands, while the South 344th Street Alternative would have the greatest degree of temporary (construction-related) impacts on wetland buffers. Among the build alternatives, the Midway Landfill

Alternative would have the least wetland impact because there are no regulated wetlands or wetland buffers within its project footprint.

The 55 mph Design Option for the curve at the northern end of the mainline tracks would affect one wetland that would otherwise be avoided by the 40 mph Alignment. Under each of the alternatives, the extent of temporary construction-related impacts on wetlands and wetland buffers would be substantially less than long-term permanent impacts.

Potential Mitigation

The proposed project would mitigate impacts on ecosystem resources in accordance with the mitigation sequencing requirements established by NEPA, SEPA, the Clean Water Act (CWA), and local critical areas ordinances. In this context, mitigation sequencing is defined as first avoiding and minimizing, then rectifying, reducing, compensating, and monitoring environmental impacts (Washington Administrative Code [WAC] 197-11-768). As described below, the project alternatives would first avoid or minimize potential impacts on ecosystems resources to the greatest degree feasible, and Sound Transit is committed to providing compensatory mitigation when avoidance is not practicable.

The avoidance and minimization of impacts was a guiding principle in the preliminary design of the project alternatives. The build alternatives for the proposed project would avoid or minimize potential impacts on ecosystems resources whenever practicable. Sound Transit would comply with applicable federal, state, and local mitigation requirements during design, construction, and post construction activities. Sound Transit would meet all regulatory requirements and implement proactive avoidance and minimization measures with best management practices in adherence with federal, state, and local regulations.

The design for OMF South was influenced by the presence and location of streams, wetlands, and potential fish habitat. The project footprint was adjusted to avoid and minimize impacts on wetlands (Wetland WFW-02 in particular), streams, riparian areas, and areas of native forest (along East Fork Hylebos Tributary in particular). Sound Transit is exploring options for reducing impacts on West Fork Hylebos Tributary without compromising the operability of the Preferred Alternative. Examples of additional strategies include minimizing vegetation clearing during construction and restoring temporarily affected areas. On-site restoration would include restoring in-stream habitat with large woody debris and planting temporarily disturbed wetlands and riparian buffers with native species.

For unavoidable long-term impacts on wetlands, streams, and their buffers, Sound Transit would develop a compensatory mitigation plan during the permitting phase, in accordance with applicable federal, state, and local requirements and guidelines. These include the federal Final Compensatory Mitigation Rule (40 Code of Federal Regulations [CFR] Part 230); interagency guidance (Wetland Mitigation in Washington State – Part 1: Agency Policies and Guidance; Ecology et al. 2021, or as updated); and the applicable local critical areas ordinances. Use of the King County In-Lieu Fee Program (Mitigation Reserves Program) or an approved mitigation bank would be considered as options for compensatory mitigation. Permittee-responsible wetland mitigation, including both on- and off-site mitigation, would also be included in the compensatory mitigation approach. Off-site mitigation areas could involve use of City-owned parcels or acquisition of properties to be restored or enhanced. Sound Transit has committed to achieving no net loss of wetland function and area on a project-wide basis.

1 INTRODUCTION

This technical report addresses ecosystem components that may be affected by the Sound Transit Operations and Maintenance Facility South (OMF South) Project. The ecosystem components addressed in this report are aquatic species and habitats; vegetation, wildlife, and wildlife habitat; and wetlands. For brevity, aquatic species and habitats, and vegetation, wildlife, and wildlife habitat are sometimes identified as aquatic resources and terrestrial resources, respectively. Discussions in this document also address threatened and endangered species. The report describes the affected environment and the expected temporary construction impacts and long-term operational impacts of the proposed alternatives, including the No-Build Alternative, on these resources. It also identifies measures intended to avoid and minimize impacts and potential compensatory mitigation for unavoidable impacts.

1.1 Project Description

Sound Transit proposes to construct and operate an operations and maintenance facility in its South Corridor (OMF South) to meet agency needs for an expanded fleet of light rail vehicles (LRVs). The need to expand LRV maintenance capacity was identified in Sound Transit 3: The Regional Transit System Plan for Central Puget Sound (Sound Transit 3). OMF South would be used to store, maintain, and deploy approximately 144 LRVs for daily service. It would provide facilities for vehicle storage, inspections, maintenance and repair, interior vehicle cleaning, and exterior vehicle washing. Additionally, the facility would receive, test, and commission new LRVs for the entire light rail system.

OMF South would also be used to accommodate administrative and operational functions, such as serving as a report base for LRV operators. Included is a Maintenance of Way (MOW) building for maintenance and storage of spare parts for tracks, vehicle propulsion equipment, train signals, and other infrastructure, in addition to storage facilities for the entire light rail system. Other facility elements would include employee and visitor parking, operations staff offices, maintenance staff offices, dispatcher work stations, an employee report room, and areas with lockers, showers, and restrooms for both operators and maintenance personnel.

Three site alternatives for the proposed project are evaluated in the Draft Environmental Impact Statement (EIS): two in Federal Way and one in Kent (Figure G3.1-1). These alternatives are named the Preferred Alternative (referred to as the South 336th Street Alternative in the 2021 SEPA Draft EIS), the South 344th Street Alternative, and the Midway Landfill Alternative, respectively.

OMF South would need to have tracks connecting to a light rail line that will be operating when the facility is planned to open, which in southern King County is the Federal Way Link Extension (FWLE). The length and location of these connecting tracks varies by alternative. The Preferred Alternative would require the construction of approximately 1.4 miles of mainline tracks and the South 344th Street Alternative would require approximately 1.8 miles of mainline tracks. The Midway Landfill Alternative is adjacent to FWLE and would connect by lead tracks directly to the FWLE mainline tracks. The Preferred and South 344th Street alternative mainlines include tail tracks that extend approximately 1,000 feet past the site to allow trains to turnaround and access the site from the south if the northern lead tracks were out of service.

Figure G3.1-1 Project Vicinity: OMF South Alternatives

The Preferred and South 344th Street alternative would also include a test track to prepare new vehicles for service. The test track would run east of and parallel to the mainline connecting the sites to FWLE (Figures G3.1-2 and G3.1-4). Figure G3.1-5 shows the mainline track options. The Midway Landfill Alternative would not include a test track because the varying grades of the existing mainline tracks make it infeasible. Due to this, this analysis assumes that LRV testing would occur on the mainline tracks.

In addition to the features identified above, the Preferred Alternative includes the extension of 18th Place S between S 340th Street and S 336th Street to replace the functions of 20th Avenue S, which would be vacated, and the extension of 21st Ave S south to S 344th Street to meet Federal Way code requirements.

This technical report was prepared to support the OMF South NEPA Draft/SEPA Supplemental Draft EIS. As such, analyses in this report meet the requirements of the National Environmental Policy Act (NEPA) and the Washington State Environmental Policy Act (SEPA). The technical report provides information that would typically be addressed in a biological assessment or other document that demonstrates compliance with the requirements of Section 7(c) of the Endangered Species Act (ESA). Further, this report addresses potential effects on Essential Fish Habitat, consistent with the requirements for federal action agencies under the Magnuson-Stevens Fishery Conservation and Management Act.

Ecosystem resources are protected by federal, state, and local regulations that govern planning, land use, and management activities affecting wetlands, streams, and fish and wildlife species and their habitats. In addition, local Indian Tribes place a high value on maintaining and restoring watershed processes and ecological conditions that will sustain salmon productivity in all watersheds of Puget Sound in perpetuity (NWIFC 2023). The regulations, along with applicable guidance from agencies and in consultation with local Indian Tribes, prescribe procedures and substantive requirements that would apply during EIS preparation and throughout construction and operation of the project. Sound Transit, therefore, considered these applicable regulations and guidance as part of this analysis.

The report attachments provide additional information on fieldwork methodologies and information that supports the ecosystems resources evaluation. Attachment G3-1 describes the wetland delineation methodology. Attachment G3-2 describes Sound Transit’s Stream Habitat Assessment Guidelines. Attachment G3-3 contains background and research information related to the wetland and stream assessments. Attachments G3-4 and G3-5 provide wetland determination data forms and Washington State Department of Ecology (Ecology) wetland rating forms. Attachment G3-6 presents photographs of the wetlands, streams, and habitat types discussed, and Attachment G3-7 includes a list of common and scientific names of plant and animal species discussed in this report.

1.2 Data Gathered

The following documents and data sources were reviewed to identify ecosystem features in the project vicinity, including the alternative footprints and potential mitigation sites:

1.2.1 Tribal

- Puyallup Tribal Fisheries annual reports for salmon, steelhead and bull trout in the Puyallup/White River Watershed (Marks et al. 2018, 2019, 2020, 2021)

1.2.2 Federal

- U.S. Department of Agriculture Natural Resources Conservation Service (NRCS) Web Soil Survey maps (NRCS 2022)
- U.S. Fish and Wildlife Service (USFWS) National Wetlands Inventory (NWI) website (USFWS 2022a)
- USFWS list of ESA-listed species and critical habitats (obtained via the online Information for Planning and Consultation planning tool) (USFWS 2022b)
- National Marine Fisheries Service (NMFS) ESA species lists (NMFS 2021)
- U.S. Geological Survey (USGS) Topographic Maps (USGS 2020)

1.2.3 State

- Washington State Department of Natural Resources (WDNR) Forest Practice Applications Review System online water typing map (WDNR 2020)
- WDNR Washington Natural Heritage Program rare plants and high-quality ecosystems datasets (WDNR 2019)
- Washington Department of Fish and Wildlife (WDFW) Priority Habitats and Species (PHS) data (WDFW 2022)
- The Northwest Indian Fisheries Commission (NWIFC) Statewide Integrated Fish Distribution (SWIFD) web map (NWIFC 2023)
- StreamNet (2021) fish distribution data
- Fish passage barrier maps from WDFW and the Washington State Department of Transportation (WSDOT) (WSDOT 2020; WDFW 2023)
- Washington Department of Fisheries catalog of Washington streams and salmon utilization (Williams et al. 1975)
- Ecology 303(d)-listed waters information

1.2.4 Local

- King County iMap interactive mapping tool (King County 2018)
- King County aerial imagery (King County 2019)
- City of Federal Way wetland inventory report (Fischer 1999)
- City of Federal Way Hylebos Creek fish use and habitat technical memorandum (HDR 2014)

- City of Federal Way Critical Areas Map (City of Federal Way 2016)
- Other studies and environmental reviews that have been conducted in or near the study area (also see studies and sources cited in resource-specific discussions):
  - Federal Way Link Extension Final Environmental Impact Statement Appendix G2: Ecosystems Technical Report (Sound Transit 2016a)
  - OMF South Scoping Summary Report (Sound Transit 2019a)
  - OMF South Alternatives Development Technical Memorandum (Sound Transit 2019b)
  - Tacoma Dome Link Extension Pre-Screening and Level 1 Alternatives Evaluation Report (Sound Transit 2019c)
  - Tacoma Dome Link Extension Level 2 Alternatives Evaluation Report (Sound Transit 2019d)
  - Tacoma Dome Link Extension Scoping Summary Report (Sound Transit 2019e)
  - Hylebos Watershed Plan (EarthCorps 2016)
  - Executive Proposed Basin Plan for the Hylebos Creek and Lower Puget Sound basins (King County 1991)

1.3 Related Laws, Regulations, and Guidelines

Project activities that may affect wetlands, aquatic species, and habitat; vegetation, wildlife species, and habitat; or threatened and endangered species in the project area are subject to the following regulations, plans, and policies:

1.3.1 Federal

- The National Environmental Policy Act, ESA Section 7, and the Magnuson Stevens Fishery Conservation and Management Act (for projects that receive funding, permits, or other authorization from a federal agency)
- Sections 404, 402, and 401 of the Clean Water Act
- Protection of Wetlands, Presidential Executive Order 11990
- Final Rule on Compensatory Mitigation for Losses of Aquatic Resources (73 Federal Register 19594, April 10, 2008)
- U.S. Army Corps of Engineers (Corps) Wetland Delineation Manual (Environmental Laboratory 1987)
- Regional Supplement to the Corps of Engineers Wetland Delineation Manual: Western Mountains, Valleys, and Coast Region (Version 2.0) (Corps 2010)
- Bald and Golden Eagle Protection Act
- Migratory Bird Treaty Act
- Treaty of Point Elliott of 1855

1.3.2 State

- SEPA (Chapter 43.21C Revised Code of Washington [RCW]) and implementing rules (Chapter 197-11 Washington Administrative Code [WAC])
- Washington State Growth Management Act (Chapter 36.70A RCW)
- Hydraulic code (Chapter 220-110 WAC)
- Protection of Wetlands, Governor's Executive Order 89-10
- Protection of Wetlands, Governor's Executive Order 90-04
- Water Pollution Control Act, Chapter 90.48 RCW
- Wetland Mitigation in Washington State (Ecology et al. 2006)

1.3.3 Regional and Local

- Sound Transit SEPA rules (Board Resolution No. R2018-17) and Sound Transit Environmental Policy (Board Resolution No. R2004-06)
- Sound Transit 3, the Regional Transit System Plan for Central Puget Sound (Sound Transit 2016b)
- Sound Transit Sustainability Plan (Sound Transit 2019f)
- Sound Transit Stream Assessment Guidelines (Sound Transit 2016c)
- Sound Transit EO Number 1: Establishing a Sustainability Initiative (Sound Transit 2007)
- City of Kent critical areas regulations (Kent City Code Chapter 11.06), amended July 21, 2015
- City of Federal Way critical areas regulations (Federal Way Revised Code Chapter 19.145), amended June 15, 2015
- King County Mitigation Reserves Program – In-Lieu Fee Program Instrument (King County 2011)
- Hylebos Watershed Plan (EarthCorps 2016)
- Executive Proposed Basin Plan for the Hylebos Creek and Lower Puget Sound basins (King County 1991)

1.4 Study Areas

Sound Transit established distinct study areas for aquatic resources, terrestrial resources, and wetlands based on proposed project footprints and areas outside the footprint that could be potentially affected by the project, such as nearby wildlife habitat affected by noise. The project footprint consists of the construction limits – the maximum extents within which clearing, grading, and the operation of construction machinery would occur – for the OMF South alternatives, as well as any areas of modifications to roadways and other existing infrastructure to accommodate the proposed facilities.

The project footprint for each OMF South alternative includes the OMF site, short segments of lead tracks that connect the site to the mainline tracks, and any new mainline tracks that would be constructed to connect the site to the southern terminus of the FWLE. The footprints for two of the build alternatives also encompass a track design option near the northern end of the mainline tracks that would reduce the curve of the mainline tracks, allowing for higher speeds. In addition to the project footprint, the study areas also include specified adjacent areas that could be affected by activities within the project footprint. Study areas for each resource are specified in Section 1.4.1 through Section 1.4.3, below. Study areas are shown in Figures G3.1-6, G3.1-7, and G3.1-8.

1.4.1 Aquatic Species and Habitat

Reconnaissance-level aquatic habitat surveys were conducted 300 feet downstream and 100 feet upstream of each water body crossing, and the entire stretch of any water body paralleling the project within 200 feet of the project limits. The survey extended to 300 feet upstream if channel configuration resulted in stream buffers overlapping the project limits.

1.4.2 Vegetation, Wildlife, and Wildlife Habitat

The study area for vegetation and wildlife habitat consists of the project footprint, plus the areas within 200 feet of the project footprint. This represents a conservative estimate of the area in which project construction and operation could affect vegetation cover and habitat quality for terrestrial wildlife. To address wildlife potentially affected by project-related noise and human activity, resource analysts also reviewed documented occurrences of sensitive wildlife species within 0.25 mile of project construction areas.

1.4.3 Wetlands

The study area for wetlands consists of the project footprint, plus the areas within 300 feet of the project footprint to account for the typical largest applicable potential buffer width for wetlands in the area. Wetlands evaluated include those features that are wholly or partly within the study area.

2 STUDY OBJECTIVES AND METHODS

This section describes the objectives and methods used to study and evaluate potential impacts on aquatic resources, terrestrial resources, and wetlands. Discussions in this section are based on the approach defined in the OMF South Environmental Methodology Report (Sound Transit 2019g).

2.1 Aquatic Species and Habitat

2.1.1 Study Objectives

The purpose of the aquatic resource investigation is to describe aquatic resources near the build alternative sites and the potential for impacts on these resources. Objectives included the following:

- Characterize all surface water bodies and riparian habitat near the project limits for each alternative.
- Identify all water bodies potentially affected (directly or indirectly) by the construction and/or operation of each alternative.
- Identify aquatic species presence and use of the surface water bodies near each project alternative.
- Identify potential effects of the proposed project on aquatic resources near each project alternative.
- Identify avoidance, minimization, and mitigation opportunities to address potential direct and indirect effects of each alternative on aquatic resources.

2.1.2 Methods

2.1.2.1 Review of Existing Maps and Documentation

Biologists reviewed existing maps and documentation to identify known streams and water bodies in the study area and vicinity (see Section 1.2, Data Gathered). When applicable, documentation of aquatic species and habitat was analyzed from Water Resource Inventory Area (WRIA), county, and subbasin reports. These streams were then verified and evaluated in the field within the field reconnaissance survey area. Existing geographic information system (GIS) data were gathered from Kent, Federal Way, and King County. Streams that extend beyond the field reconnaissance survey area and other previously mapped streams outside of the WSDOT or other public rights-of-way were also incorporated into the GIS database. Background information about riparian vegetation, physical in-stream habitat, biological connectivity, water quality and quantity, stream typing, and fish presence and habitat use was collected during the pre-field review phase.

Species known to use habitats in the study area are those whose presence is documented by the information sources identified in Section 1.2, Data Gathered, as well as species observed during site visits conducted for this analysis. Species whose known or expected distribution encompasses the study area and that are associated with habitat types in the study area are considered potentially present.

Aquatic habitats and species of concern are those with a regulatory status that prompts individual attention through federal, state, and/or local permitting processes. Specific habitat types that receive consideration under local critical areas regulations are also identified. Species and habitats of concern include the following:

- Species listed or proposed for listing as threatened or endangered under the ESA, as well as proposed or designated critical habitat for those species
- Species for which fish and wildlife habitat conservation areas (FWHCAs) have been established under local critical areas rules
  - The Kent City Code (Section 11.06.710) identifies the following as FWHCAs:
    - Areas with the documented presence of federally or state-listed endangered, threatened, or sensitive species
    - Areas with the documented presence of species or habitats identified in the WDFW PHS database, current city habitat maps, or other relevant databases
    - Naturally occurring ponds
    - Waters of the state (including streams and lakes)
  - The Federal Way Revised Code (Section 19.145.260) identifies the following as FWHCAs:
    - Areas with which federally listed endangered or threatened species or state-listed endangered, threatened, or sensitive species have a primary association
    - State priority habitats and areas associated with state priority species, as identified by WDFW
    - Habitats and species of local importance (Federal Way has not identified any habitats or species of local importance)
    - Streams
    - Lakes

2.1.2.2 Field Reconnaissance and Delineation

The aquatic species and habitat assessment focused on key habitats and aquatic features that may be affected by the project and that are directly related to ecological functions that support aquatic ecosystems. After collecting and reviewing existing information, biologists conducted detailed field reconnaissance and delineation surveys within the study area to identify and confirm ecosystem resources that could be affected. Biologists conducted formal delineations (flagging and professional land surveying) of the ordinary high water line (OHWL) of East Fork Hylebos Tributary, and its associated wetlands, on the east side of the Preferred and South 344th Street alternatives due to the anticipated high level of interest from agencies, Tribes, and the public and to aid design work. Other locations of East Fork Hylebos Tributary and other Hylebos Creek tributaries were not delineated for this analysis and habitat conditions were documented at a reconnaissance level.

Sound Transit’s Stream Habitat Assessment Guidelines (Sound Transit 2016c) (Attachment G3-2) were used to determine the level of information that should be collected for each identified stream. In accordance with the guidelines, research and field surveys were conducted to identify, map, and describe aquatic species and the condition of in-stream and riparian habitats within the study area. The Phase 1 project approach (planning-level study) was used to provide analysis for NEPA, SEPA, and ESA coordination. Within the Phase 1 approach, the project used the Track A methods for assessing aquatic area impacts where property access is not granted and for all streams other than East Fork Hylebos Tributary. Track B methods were used on East Fork Hylebos Tributary and Sound Transit, WSDOT, or other publicly owned right-of-way/easement areas. Track A is typically used where access is limited or impacts are not anticipated; Track B is typically used where access is possible and impacts are anticipated (Sound Transit 2016c).

Habitat was assessed with the assumption that anadromous fish may one day be able to enter stream reaches where no natural barriers exist, even if human-created barriers currently prevent access. Using information gathered during field reconnaissance and from sources such as Tribes, local jurisdictions, WSDOT, and fish passage barrier maps maintained by WDFW, biologists evaluated the accessibility of each stream in the study area, identifying downstream impediments to fish passage.

Biologists classified streams according to the interim water typing definitions in WAC section 222-16-031, and the applicable stream classification systems in the city of Kent's Environmental Management Code and the city of Federal Way's Zoning and Development Code. The biologists then identified regulatory buffers based on each stream's water type or classification.

2.2 Vegetation, Wildlife, and Wildlife Habitat

This section identifies the objectives of the investigations into terrestrial resources in the study area and describes the methods used to characterize the vegetation and wildlife habitats in the project vicinity and to identify potential impacts on those habitats. It also includes a discussion of threatened and endangered species, species of concern, and high-value habitats in the vegetation and wildlife study area.

2.2.1 Study Objectives

The purpose of the investigation into terrestrial resources was to characterize the existing condition of vegetation and wildlife habitat in the study area and to identify species of concern that may be affected by the proposed alternatives. Study objectives included the following:

- Identify, map, and describe the existing conditions of the vegetation communities and wildlife habitat resources in the study area.
- Characterize the potential for species of concern to use habitats in the study area.
- Evaluate the potential effects of each alternative on vegetation, wildlife, and wildlife habitat.
- Identify potential measures to avoid, minimize, or compensate for unavoidable adverse effects.

2.2.2 Methods

To establish the basis for the analysis of effects on vegetation, wildlife, and wildlife habitat, biologists delineated and classified land cover on aerial photographs and visited a sample of these areas during the field reconnaissance surveys. Land cover types were identified and classified based on study area-specific refinements of the structural categories defined by Johnson and O'Neil (2001). Forest composition, relative age, native species cover, and habitat features were key attributes in determining vegetation types. Vegetation data, including dominant plant species composition, were gathered and classified by habitat type using field observation, aerial photographs, and pertinent literature.

To support the analysis of effects on wildlife, the biologists identified wildlife species associated with the land cover types in the study area, as well as specific habitat elements within each cover type. Biologists used geospatial data from the WDFW PHS Program and the WDNR Natural Heritage Program to identify documented locations of priority species, priority habitats, rare plant populations, and high-quality ecosystems in the study area. Biologists also reviewed site-specific wildlife data, including bird surveys (e.g., Opperman et al. 2006, eBird 2022), supplemented with data gathered during field visits.

Wildlife habitat values were not evaluated for each occurrence of each land cover type along the project corridor but instead were assigned to the cover type as a whole. Habitat value within a cover type at a specific location can vary and depend on several factors, such as size of the area; degree of fragmentation or isolation; presence of (or proximity to) other valuable habitat; potential role as a travel corridor; level and type of human disturbance; diversity of plant species; presence of multiple cover layers (i.e., tree, shrub, and herbaceous layers); presence of threatened, endangered, or sensitive species; and extent of invasive weeds.

Species known to use habitats in the study area are those whose presence is documented by the information sources identified in Section 1.2, Data Gathered, as well as species observed during site visits conducted for this analysis. Species for which known or expected distribution encompasses the study area and that are associated with habitat types in the study area are considered potentially present.

Plant and animal species of concern are those with a regulatory status that prompts individual attention through federal, state, and/or local permitting processes. Specific habitat types that receive consideration under local critical areas regulations are also identified. Species and habitats of concern include the following:

- Species listed or proposed for listing as threatened or endangered under the ESA, as well as proposed or designated critical habitat for those species.
- Species for which FWHCAs have been established under local critical areas rules.
  - The Kent City Code (Section 11.06.710) identifies the following as FWHCAs:
    - Areas with the documented presence of federally or state-listed endangered, threatened, or sensitive species
    - Areas with the documented presence of species or habitats identified in the WDFW PHS database, current city habitat maps, or other relevant databases
    - Areas with unusual nesting or resting sites, such as heron rookeries or active nests of raptors that are included in the listing categories specified above
    - Naturally occurring ponds
    - Waters of the state (including streams and lakes)
  - The Federal Way Revised Code (Section 19.145.260) identifies the following as FWHCAs:
    - Areas with which federally listed endangered or threatened species or state-listed endangered, threatened, or sensitive species have a primary association
    - State priority habitats and areas associated with state priority species, as identified by WDFW
    - Habitats and species of local importance (the city of Federal Way has not identified any habitats or species of local importance)
    - Streams
    - Lakes
- Bird species protected under the Migratory Bird Treaty Act

2.3 Wetlands

2.3.1 Study Objectives

The wetland study was conducted to identify, map, and describe wetlands in the study area. Study objectives included the following:

- Thoroughly research and assess field site conditions with respect to wetlands
- Evaluate the effects of the alternatives on these features
- Identify potential measures to avoid, minimize, or compensate for unavoidable adverse effects on wetlands

2.3.2 Methods

Wetland assessments are based on background research (see Section 1.2, Data Gathered) and analysis of existing information and datasets, combined with field surveys to document current conditions. Wetland assessments include both delineated and estimated extents for all wetlands in the study area. The extents of wetlands on properties lacking access were estimated by using remote sensing and best professional judgment. Vegetation and potential wetlands in areas where rights of entry had not been obtained were identified based on field reconnaissance from public areas; current local, state, and federal habitat maps and reports; and the examination of aerial photographs. Documented wetlands from other projects or sources were evaluated and, where appropriate, included in the wetland findings.

Where property access was obtained, wetland boundaries were formally delineated. While a formal delineation level of study is not required at this stage of the environmental review process, Sound Transit felt that the interest expressed during the scoping period justified collecting detailed information, particularly to advise the engineering design team and avoid resources where possible. This detailed work was conducted to provide comprehensive information in areas with an anticipated high level of interest from agencies, Tribes, and the public (specifically, areas associated with tributaries to Hylebos Creek). Other wetlands in the study area were identified at the reconnaissance level in which wetland boundaries were not formally delineated. Almost all wetlands in the study area are associated with tributaries of Hylebos Creek, and property access was obtained for almost all parcels where access was needed. As a result, most wetlands in the study area were delineated.

Wetland boundaries were estimated or delineated using methods outlined in the Corps Wetland Delineation Manual (Environmental Laboratory 1987) and indicators defined in the Regional Supplement to the Corps of Engineers Wetland Delineation Manual: Western Mountains, Valleys, and Coast Region Version 2.0 (Corps 2010). Detailed methodology for wetland assessments is included in Attachment G3-2. Observations of existing conditions and characteristics were recorded for each wetland and associated buffer.

Wetlands were classified according to the USFWS (Cowardin et al. 1979, FGDC 2013) and hydrogeomorphic (Brinson 1993) classification systems. These were rated according to local jurisdiction critical area ordinance and the Washington State Wetland Rating System for Western Washington: 2014 Update (Hruby 2014). The width of each wetland’s regulatory buffer was identified based on the wetland’s rating and habitat function score, as required under the critical area code of the local jurisdiction. All wetland ratings, and therefore associated regulatory buffer widths, are preliminary and are subject to change. Wetland functions were based on using the Washington State Wetland Rating System for Western Washington: 2014 Update (Hruby 2014).

Wetland determination forms and rating forms are included in Attachment G3-4 and G3-5, respectively. Representative photographs of wetlands in the study area are in Attachment G3-6. Scientific names of plants and animals are presented in Attachment G3-7.

2.4 Impact Assessment Methods and Assumptions

Resource analysts evaluated long-term and temporary (construction-related) impacts on ecosystem resources. The following subsections describe the process by which direct, indirect, and cumulative impacts on each ecosystem component were identified, as well as the supporting assumptions for the impact analyses.

2.4.1 Direct Impacts

For this analysis, the design team identified a permanent impact footprint based on the preliminary (less than 10 percent) design for the South 344th Street Alternative and Midway Landfill Alternative OMF sites, including lead tracks, mainline tracks, and other project features that would result in long-term impacts on ecosystem resources. The design level of the Preferred Alternative has been advanced since publication of the 2021 Draft EIS. This analysis has been updated to assess the refined design, which is near 20 percent. The design team also defined a temporary impact footprint, which encompasses the permanent impact footprint and surrounding areas where vegetation clearing and ground-disturbing work are likely to be required for project construction. Areas outside the permanent impact footprint but within the temporary impact footprint would be expected to be restored to pre-project conditions, or better, following construction. These footprints were overlain on mapped locations of streams, wetlands, and vegetation cover types to determine the extent of the potential impacts of the alternatives on ecosystem resources. Following identification of the Preferred Alternative, the long-term and temporary impact footprints for that alternative were refined.

Direct impacts on aquatic species and habitat were determined by evaluating the length (in linear feet) of each water body and the acreage of riparian buffers that would be altered or eliminated for each alternative. Calculations of riparian buffer impacts were based on impacts to functional buffers. The functional buffer of a stream is the width of its standard regulatory buffer or the distance to the nearest edge of a developed area, whichever is smaller. In other words, the functional buffer does not include areas where riparian functions are compromised by high-intensity land uses and development such as buildings, parking lots, or roads. This approach is consistent with the critical areas regulations of many local jurisdictions, which do not require mitigation for impacts to developed areas within the standard regulatory buffer distance from streams.

Direct impacts on aquatic species were assessed qualitatively by considering such factors as the regional importance of the resident and anadromous fish species resource, fish habitat value (such as its role as a migration corridor or spawning), degree of connectivity and loss of habitat following project implementation, overall habitat quality, and potential for enhancing or restoring aquatic habitat or connectivity. Construction and operational impacts on aquatic species from water quality degradation and loss of habitat were also assessed. Potential long-term impacts on threatened and endangered species were determined, including direct mortality, disturbance and displacement effects, and loss or degradation of habitat. The assessment also included a review of potential effects on Essential Fish Habitat.

Potential impacts of each alternative on terrestrial resources were quantitatively evaluated by evaluating the acreage of major vegetation types that would be temporarily or permanently affected by project construction and operation. Impacts on rare plant populations were determined by evaluating the acreage of any mapped populations that would be affected by construction or operation of each alternative. The potential for the introduction or removal of noxious or invasive plant species was also evaluated.

Potential impacts on wildlife, including species of concern, were also assessed qualitatively by considering such factors as the regional importance of the resource, wildlife habitat value of affected areas (such as its role as a wildlife movement corridor), degree of fragmentation and loss of the habitat following project implementation, overall habitat quality, and the potential for enhancing or restoring unique plant communities or wildlife habitat or connectivity. Evaluations of the potential for increased human access, noise, and light to affect sensitive wildlife species were based on the proximity of project features and work sites to known locations of sensitive sites such as breeding areas or communal roosts.

Impact analyses on wetlands and buffers were based on direct impacts from both long-term effects (filling or other permanent displacement) and short-term construction-related effects (vegetation clearing). If a contiguous wetland lies partially within and partially outside the project limits, project effects on the portion of the wetland not directly affected by the project were assessed using guidance in Wetland Mitigation in Washington State – Part 1: Agency Policies and Guidance (Ecology et al. 2021). As with riparian buffers, calculations of impacts to wetland buffers were based on impacts to functional buffers. If a wetland were eliminated, the surrounding area would no longer serve as a wetland buffer and impacts on that surrounding area would not constitute wetland buffer impacts. Elimination of a wetland and actual buffer impacts would be determined through the permitting process. For this analysis, calculations include buffers of wetlands that may be permanently eliminated by project construction and therefore likely represents an over-estimation of buffer impacts.

2.4.2 Indirect Impacts

Indirect impacts are project-related effects that are reasonably foreseeable but separated from project implementation by distance or time. Examples may include changes in land use patterns, population density, or water quality in the areas affected by the project. Indirect impacts may also occur through the implementation of mitigation measures for other environmental impacts, or through supporting projects that are not yet defined or considered part of the project alternatives. Indirect impacts on ecosystem resources were analyzed qualitatively in this document.

2.4.3 Cumulative Impacts

Cumulative impacts are the effects of the project when combined with other past, present, and reasonably foreseeable future actions. The cumulative impacts analysis incorporated the effects of Sound Transit’s other proposed light rail extension projects, including the FWLE project and the Tacoma Dome Link Extension (TDLE) project which are assumed to be part of the No-Build Alternative. Reasonably foreseeable projects include the WSDOT State Route (SR) 509 Completion project, WSDOT’s I-5/SR 161/SR 18 Triangle project, the Creekside Commons Townhomes development, and the Federal Way City Center Access project.

2.4.4 Analysis Assumptions

The process of analyzing and estimating project impacts requires a series of assumptions regarding the physical extent of impacts, the duration of impacts, site restoration following construction, and measures that would be implemented to avoid or minimize potential impacts.

This analysis also includes temporary construction impacts and permanent operational impacts within the project right-of-way.

For the impact analysis, Sound Transit assumes that all aquatic resources, terrestrial resources, and wetlands within the limits of the specific facilities proposed under each alternative, including the area within the footprint of the mainline and lead tracks, would be modified during construction. In most areas, the ecosystem functions of such areas would be substantially degraded or eliminated. In the case of streams within the project footprint, Sound Transit would minimize impacts on streams by avoiding, to the degree feasible, enclosing any surface-flowing stream channels in new culverts or pipes.

Compared to the impacts of site facilities and at-grade tracks, the impacts of elevated portions of the mainline, lead, tail, and test tracks (under the Preferred Alternative or the South 344th Street Alternative) would be less severe. These structures would be relatively narrow (typically 20 to 30 feet wide) and generally more than 15 feet above the ground surface. Vegetation would be able to grow in such areas, although the density and variety of vegetation would be limited by the reduced availability of sunlight and water. For operational safety, trees and other tall vegetation would not be allowed to grow near the mainline, lead, tail, or test tracks. Sound Transit's Design Criteria Manual specifies a clear zone of at least 11 feet between the guideway edge and the edge of a tree's canopy. Shorter-stature trees may be allowed under elevated guideways, provided there is at least 5 feet of vertical clearance between the top of the tree and the height of the support column. For this analysis, the permanent impact footprint is defined to include a 15-foot clear zone from the edges of track segments. This represents an estimate of the areas where the alternatives would likely have long-term impacts on vegetation.

Based on site-specific conditions, retaining walls would be built in some areas to minimize disturbance to the aquatic features and their buffers. To allow maintenance access and to avoid damage, trees and other large vegetation would not be allowed to grow near the base or top of the walls.

The permanent and temporary impact footprints developed for this analysis represent Sound Transit's best estimates of the areas that may be affected by the OMF South alternatives. These estimates are conservative. For example, clearing of all areas within the temporary impact footprint may not be necessary, but analyses of construction-related impacts are based on the assumption that the entire temporary impact footprint would be cleared for construction. In addition, the permanent impact footprint may include some areas where project components could be scaled down or eliminated as the project design progresses from its current, preliminary status. Moreover, not all areas within the project footprint would be converted to structures or hard surfaces. Some vegetated areas, for example, would be converted to other land cover types, such as landscaping or stormwater facilities. In other areas, existing hard surfaces may be converted to vegetation.

By applying a consistent set of assumptions for all of the alternatives, these footprints allow analysts to evaluate the relative degree of the potential impacts of the alternatives on ecosystem resources. Actual anticipated impacts would be determined when an alternative is selected to be built and the project design is sufficiently advanced to undergo permitting review. Additional field work would be conducted for the selected alternative to refine project impacts.

Vegetation in temporarily disturbed areas (e.g., in construction access areas and related rights-of-way) would be restored after construction is complete. Site restoration would include replanting disturbed areas with appropriate native vegetation immediately following construction. The length of time required for recovery of ecological functions would vary depending upon the intensity of the temporary impact (e.g., vegetation clearing *versus* temporary fill), as well as the type, age, and diversity of the existing plant community in the affected areas. The estimated extent of areas that would be temporarily affected by project construction is based on mapping provided by the project design team.

OMF South would be designed and constructed in compliance with all applicable federal, state, and local regulations. Sound Transit assumes the overall extent and magnitude of potential temporary construction impacts would be controlled by the types of construction activities and by the implementation of best management practices (BMPs; see Section 5.1.1, Avoidance and Minimization During Design Development and Section 5.1.2, Construction Best Management Practices). These BMPs would be designed to accommodate site-specific characteristics such as the widths of wetland and stream buffers.

Adverse effects on ecosystem resources would be avoided or minimized first through the project design process and through careful implementation, monitoring, and maintenance of BMPs during project construction and operation. Compensatory mitigation for unavoidable adverse effects would be implemented in accordance with permit requirements and local critical areas regulations (see Section 5, Mitigation Measures).

3 AFFECTED ENVIRONMENT

The alternative sites characterized within the affected environment include the Midway Landfill Alternative in Kent and two sites in Federal Way, the Preferred and South 344th Street alternatives. The Preferred and South 344th Street alternatives each include the two alternatives for the mainline tracks that would connect the sites to the Federal Way Downtown Station, known as the 40 mph Alignment and the 55 mph Design Option. The site footprints in Federal Way, including the mainline tracks, are largely overlapping and are described as one unit for the purposes of simplifying the description of resources in the affected environment section.

3.1 Aquatic Species and Habitat

This section identifies aquatic species and habitats that may be affected by the construction and operation of OMF South. The study area is in an urban area where aquatic habitats have been highly modified by past development. The proposed facilities lie within areas disturbed by the construction of I-5, the Midway Landfill, and commercial, institutional, and light industrial development. Several streams in the study area have been placed partially in conveyance systems consisting of pipes, stormwater facilities, and ditches, interfering with natural flow patterns and processes, such as groundwater recharge and floodplain connectivity. The surrounding areas are dominated by commercial, institutional, residential, and light industrial development with extensive areas of impervious surface.

The portion of the study area in Kent drains to the North Fork McSorley Creek in WRIA 9, the Duwamish-Green watershed. The study area in Federal Way drains to Hylebos Creek in WRIA 10, the Puyallup-White watershed.

Many species of fish, both native and introduced, inhabit WRIAs 9 and 10. Discussions in this document focus on salmonids – anadromous salmonids in particular – because these species are a management concern due to habitat degradation and population declines. Salmonids in WRIAs 9 and 10 are a mix of native and introduced stocks. For example, sockeye salmon that spawn in some areas appear to be descendants of introduced fish, while those in other areas may be native fish (Hendry et al. 1996). Little genetic information is available for salmon originating from smaller independent tributaries to Puget Sound, such as McSorley Creek and Hylebos Creek. No unique stocks have been identified in Hylebos Creek or McSorley Creek (WDFW and WWTT 1994). However, LeClair (1999) determined that fall chum salmon stocks occurring in Hylebos Creek are of an unknown stock origin. King County (1991) identified regionally and locally important resource areas in the Hylebos Creek basin. Such areas are defined as drainage basins, wetlands, or stream reaches that are important to the viability of fish and wildlife populations as biological, social, and/or economic resources. No regionally or locally important resource areas are mapped in the study area (King County 1991).

An important aspect of documenting fish distribution into streams within each alternative’s study area is the presence of both natural and human made barriers that obstruct or limit use of streams by all fish species. In this assessment, the focus is primarily on salmonids, given their cultural, economic, and recreational significance, but also because many of the populations are experiencing significant declines. Many salmonids are currently listed as threatened or endangered species under the ESA. A significant contributing factor to salmonid population declines is the inability to reach historically accessible habitat, reproduce, and complete other necessary life history requirements due to human made barriers (e.g., improperly constructed culverts or dams). WDFW has evaluated thousands of potential barriers across Washington and maintains a database that applies a percent fish passability rating to each of the assessed barriers. The percent passability is estimated for all fish passage features and uses a combination of professional judgment and species ability to negotiate water surface drop, velocity, and depth. A feature may be evaluated as a total barrier (0 percent passable), a partial barrier (33 percent passable; some passage), a less severe partial barrier (67 percent passable), or a non-barrier (100 percent passable; passable during all times when flow is present, up to the high fish passage flow). The guidance is based upon the abilities of a 15.24-centimeter (6-inch) trout, so it should not be construed as an absolute value for all salmonid species and life stages. The percent passability estimates are intended to represent general categories of passability, not actual estimates of the number of fish that may pass. The percent passability is one factor used for prioritizing barrier correction (WDFW 2019). This document includes results of WDFW's assessment, primarily as a means of documenting the probability of fish presence when fish distribution data are unavailable from other resources, such as SWIFD, StreamNet, or SalmonScape.

3.1.1 Streams in the Study Area

Consistent with Sound Transit's stream habitat assessment guidelines (Sound Transit 2016c), this subsection describes the streams in the study area, or those potentially affected by the project, and provides information about the following key aquatic habitat elements:

- Riparian vegetation
- Physical in-stream habitat
- Biological connectivity
- Water quality and quantity
- Fish presence and habitat use, and stream typing

The proposed OMF South facilities (including lead tracks) and mainline tracks would cross or parallel two streams in the study area: East Fork Hylebos Tributary and West Fork Hylebos Tributary. Both streams are tributaries to Hylebos Creek, an independent tributary that discharges to the Hylebos Waterway along the eastern shore of Puget Sound's Commencement Bay in Tacoma. A third stream (North Fork McSorley Creek) is a tributary to McSorley Creek, an independent tributary that discharges to the eastern shore of Puget Sound in Saltwater State Park in Des Moines. Figures G3.3-1 through G3.3-3 show stream locations, conditions (surface-flowing or piped), and fish passage barriers. Table G3.3-1 summarizes regulatory information for the streams either in the study area, or potentially affected by the project.

Table G3.3-1 Summary of Streams in the Study Area

Stream Name	Stream Index No.[1]	State Interim Water Type[2]	Local Jurisdiction	Local Jurisdiction Stream Classification	Local Jurisdiction Buffer Width[3]
East Fork Hylebos Tributary	10.0016A	3	Federal Way	F	100
West Fork Hylebos Tributary	10.0014C	3	Federal Way	F	100
North Fork McSorley Creek[4]	09.0382	NA	N/A	F	NA

Notes: Streams listed from north to south.

(1) WRIA identification numbers according to Williams et al. (1975) and King County (1990)

(2) WAC 222-16-031

(3) Federal Way Municipal Code 19.145.270 (Revised 10/15/2019)

(4) No surface-flowing portion of North Fork McSorley Creek is within the study area; however, because the Midway Landfill Alternative may potentially discharge stormwater to the stream, it is included in this analysis.

3.1.1.1 East Fork Hylebos Tributary

East Fork Hylebos Tributary flows through the eastern portions of both the Preferred and South 344th Street alternatives west of I-5. Surface-flowing segments near the stream's headwaters are within the study area for both mainline track options. Before the construction of I-5 in 1965, the reaches of this stream that flow through the study area were the headwaters of Tributary 0013 in the West Fork Hylebos Creek subbasin. Construction of the I-5 system created a drainage catchment that permanently diverted the tributary into the East Fork Hylebos Creek subbasin (WSDOT and FHWA 2009).

East Fork Hylebos Tributary originates on the east side of I-5 north of S 320th Street in Federal Way. The stream is piped under the freeway and beneath the King County Park and Ride lot, emerging in the study area in Belmor Park Golf and Country Club (Belmor). In this area, a defined channel is more consistently present in surface-flowing segments of the stream. The stream flows south for approximately 2.1 miles before turning east near S 356th Street and crossing underneath I-5, flowing south of SR 161 (Enchanted Parkway S) to join other tributaries to form East Fork Hylebos Creek. The stream channel in the study area is low gradient, straight, and confined between I-5 and residential, commercial, institutional, and light industrial developments. Approximately 8,500 linear feet of the stream are within the study area for the Preferred and South 344th Street alternatives. Of that length, approximately 6,450 linear feet flow in open channels and 2,050 linear feet are piped (Figures G3.3-1 and G3.3-2).

East Fork Hylebos Creek continues on the east side of I-5, flowing through the city of Milton, and turns to the southwest along the Interurban Trail until it converges with West Fork Hylebos Creek near the Porter Way crossing of I-5. From this point, the stream continues south as Hylebos Creek, crossing back across to the west side of I-5 and discharging to the Hylebos Waterway in Tacoma.

Before the mid-19th century, the Hylebos Creek watershed is thought to have been one of the most productive small, salmon-bearing streams draining to southern Puget Sound (King County 1990). Development of the region began in 1851, when the first Euro-American settlers began arriving in the Tacoma area. Since that time, extensive forest cover has been removed, wetlands have been drained and filled, stream channels have been modified, and forested areas have been converted to impervious surfaces. Currently, Hylebos Creek is located in one of the most heavily urbanized watersheds in the state (Kerwin 1999). Most of East Fork Hylebos Tributary is in Federal Way, where population growth continues. Land in Federal Way is largely built out, with most remaining undeveloped lands containing environmentally sensitive areas such as streams and wetlands and their regulatory buffers.

The following subsections describe key habitats and stream features that are directly related to ecological functions supporting stream ecosystems and may be affected by the project, consistent with the stream habitat assessment guidelines established by Sound Transit (2016c).

Riparian Vegetation

Riparian vegetation along some portions of East Fork Hylebos Tributary in the study area is dominated by native forest and wetlands. In other areas, native riparian vegetation has been replaced with landscaping, mowed grasses, or invasive shrubs.

In the area near the Preferred and South 344th Street alternatives, riparian vegetation is characterized as a mixed deciduous and coniferous forest. The forested canopy consists of bigleaf maple, black cottonwood, Oregon ash, Douglas-fir, red alder, Sitka willow, and western redcedar. The understory vegetation consists of cascara, vine maple, salmonberry, beaked hazelnut, sword fern, osoberry, red-twig dogwood, skunk cabbage, lady fern, stink currant, red elderberry, Himalayan blackberry, trailing blackberry, stinging nettle, and reed canarygrass. A large portion of the riparian corridor contains wetland habitats and associated vegetation. The left bank riparian zone in this area includes the fill slope for I-5 and is dominated by upland-associated vegetation, such as Douglas-fir. The right bank riparian zone is dominated by more typical riparian species, as described above.

Because the riparian corridors in the study area are dominated by native forest and wetlands that support a diversity of functions, they are considered high-quality riparian habitat. The functions provided include fish and wildlife habitat provision; food chain support; water temperature maintenance; infiltration; groundwater recharge and discharge; sediment delivery, transport, and storage; organic matter input; nutrient and pathogen removal; and stream channel formation and maintenance. In other parts of the study area, riparian habitat along East Fork Hylebos Tributary has been degraded through the conversion of native and structurally complex habitats into landscaping, mowed grasses, or invasive shrubs.

The width of the vegetated riparian area south of S 336th Street ranges from 130 feet on the right bank to 150 feet on the left bank. Starting approximately 500 south of S 336th Street, the width of the functional riparian buffer is limited by a retaining wall along the eastern boundary of the Christian Faith Center property. The wall parallels the stream for approximately 500 feet. The width of the vegetated area between the retaining wall and I-5 is approximately 230 to 260 feet.

Downstream of the Christian Faith Center (until the stream reaches the culvert upstream of the WSDOT stormwater facility north of S 344th Street), the stream is confined by I-5 on the east and developed properties to the west. Similar to the reach a little farther north, the width of the functional riparian buffer in this area is limited by a retaining wall along the eastern boundary of the Ellenos Yogurt parcel. The wall parallels the stream for approximately 350 feet. The width of the vegetated area between the retaining wall and the cleared right-of-way for I-5 in this area is approximately 80 feet. Where the stream resurfaces in the cloverleaf interchange between southbound I-5 and SR 18, the vegetated riparian area varies between 100 and 150 feet, narrowing as the stream approaches culverts on the upstream and downstream ends.

Canopy cover was measured every 150 feet along the surveyed stream length. The average stream canopy cover between S 336th Street and S 344th Street is 75 percent. Stream canopy cover in the onramp from southbound I-5 to westbound SR 18 is 79 percent; stream canopy cover in the onramp from southbound I-5 to eastbound SR 18 is 41 percent.

Physical In-Stream Habitat

As observed in the field, habitat in East Fork Hylebos Tributary is degraded. Glides (one of the least desirable habitat types for salmonids) make up more than 50 percent of the stream length between S 336th Street and S 344th Street. Riffles constitute approximately 30 percent of stream habitat in the study area, followed by pools (15 percent) and wetlands (4 percent). The average channel width for the stream within this reach is 8 feet.

The gradient of the stream is low, generally 1 percent or less. As a result, fine sediments have accumulated over time, resulting in the shallowing and widening of the streambed. Dense patches of reed canarygrass have become established in some low-energy areas, exacerbating the deposition of fine sediments. Fine sediments, including sand and silt, dominate the substrate composition in the study area. Patches of gravel are present, primarily in riffle areas; in most areas, however, these gravels are 30 to 40 percent embedded with fine sediments. Pebble count data collected from representative riffle habitats indicate that medium- to coarse-sized gravels (8 mm to 64 mm) are dominant and small gravel and small cobble are subdominant.

Channel sinuosity in the study area is low. Much of the channel is confined within a straight and uniform (ditch-like) channel profile. Reaches with a more natural, meandering profile are rare and short. Fine sediment deposition throughout the reach in the study area is raising the streambed elevation, resulting in frequent channel overtopping and the formation of backwaters and high-flow channels adjacent to the primary channel. During higher flows, the stream overtops its banks quickly and engages the floodplain and riparian wetlands. Large woody debris (LWD) is present in and near the stream channel, creating the potential for increased habitat complexity.

Key restoration opportunities in East Fork Hylebos Tributary in the study area include removal of fish passage barriers, human-made debris, and garbage; removal and control of invasive plant species; LWD installation; and possible channel reconfigurations to increase pool quantity and quality, stream sinuosity, stream flow infiltration, temperature moderation (thermal protection), and overall habitat complexity.

Table G3.3-2 summarizes the characteristics of physical in-stream habitat of East Fork Hylebos Tributary in the study area, using the metrics and measurements recommended by Sound Transit (2016c).

Table G3.3-2 Characteristics of Physical In-Stream Habitat for East Fork Hylebos Tributary in the Study Area

Parameter	Metric/Measurement	Condition in Study Area
Channel Form and Profile	Macrohabitat – habitat type	Habitats in the study area were dominated by glide habitat, followed by low gradient riffle habitat, pools, and wetlands.
	Macrohabitat – pool characteristics	No pools in the project area exceeded 2 feet in depth with average residual pool depths of 0.71 feet throughout the corridor. The intermittent nature of the stream, combined with moderately infiltrative soils, indicates that while pools may have some moderate ability to retain water, this water quickly dries up.
	Stream Slope	East Fork Hylebos Tributary is a low-gradient stream within the project area. Stream slopes ranged from 0.4 percent to 1.1 percent.
	Stream Patterns	Straight
	Confinement	The entrenchment ratio for all measurements was > 2.2, indicating that East Fork Hylebos Tributary is only slightly entrenched and has good connectivity to the adjacent floodplain.
	Channel Dimension/Shape	East Fork Hylebos Creek is characterized by a shallow U-shaped channel with an average bankfull width of 10.5 feet and an average bankfull depth of approximately 1.2 feet.

Table G3.3-2 Characteristics of Physical In-Stream Habitat for East Fork Hylebos Tributary in the Study Area (continued)

Parameter	Metric/Measurement	Condition in Study Area
Streambank Condition	Stability	Streambanks are typically stable with some areas of low scour.
	Bank Hardening/Revetments	Shoreline armoring is largely absent from the streambanks except for riprap armoring at many of the culvert crossings.
Substrate/ Sediment	Particle Frequency	Representative pebble counts were conducted at several riffles and pool tail-out locations throughout the assessed reaches. In general, gravels (particles ranging from 8-64 mm) were dominant, with small gravel (2-8 mm) and small cobble being subdominant (64-128 mm).
	Percentage of Fine Sediments/Embeddedness	Gravels, where present, are typically between 30 and 40 percent embedded with fines.
Large Woody Debris (LWD)	LWD Presence, Frequency, and Location	Approximately 71 pieces of LWD were observed over the 3,234 feet of assessed stream length. This equates to a density of 115 pieces per mile. A total of 66 percent of pieces were in the water, 31 percent spanned the channel, and 2 percent were not in the water but were below the bankfull elevation.
	Debris Jams	No debris jams were observed throughout the assessed reach.
	LWD Size	Coniferous logs averaged 28 feet in length and 12.2 inches in diameter. Deciduous logs averaged 23 feet in length and 8.1 inches in diameter.
	Age and Type	31 percent coniferous logs, 18 percent coniferous root wads, and 51 percent deciduous logs. The coniferous logs were typically in better condition with an average decay class of 2, which indicates the bark was typically still intact and the log maintained its original color. The majority of deciduous logs had a decay class between 3 and 4, meaning that most of the bark had gone and deterioration was advanced or advancing.
Cover and Refuge	Pool Quality	Pools in the project area have pool quality index values ranging from 2 to 4, with the majority being between 2 and 3. Pools, where present, were small, lacked sufficient depth, and had low to moderate cover.
	Undercut Banks	Undercut banks were rare throughout the reach. Undercut banks, where present, were shallow and provided little to no cover.
	Off-channel/Side-channel Habitat	The surveyed reach was devoid of off-channel habitat, such as side channels and beaver dams.
	In-stream Cover/Protection	Other than LWD, no boulders or aquatic macrophytes were present that would provide any type of cover. The intermittent nature of the stream prevents the colonization of the stream channel by aquatic macrophytes. Reed canarygrass is present in some areas; however, where present, this material tends to choke the channel and divert water around the channel and is effectively inaccessible to rearing fish.

Note: *PQI = Pool Quality Index for Puget Sound Lowland Streams (modified from Platts et al. 1983)

Biological Connectivity

Numerous barriers to fish passage exist within and downstream of the study area. Table G3.3-3 summarizes the status of known fish passage barriers in East Fork Hylebos Tributary within and downstream of the study area for the Preferred and South 344th Street alternatives. Under current conditions, access to the study area is obstructed by two culverts downstream of the study area that are identified as total barriers to fish passage. Access is further limited by three partial barriers and one structure that WDFW was unable to evaluate (Table G3.3-3). Notably, WSDOT is developing plans for the correction of one total barrier and three partial barriers downstream of the study area, as well as one total barrier and two partial barriers within the study area (Table G3.3-3). It is assumed for this analysis that those barriers will have been removed before work on the OMF South project would begin under any of the build alternatives. Even with the removal of those seven barriers, several barriers (including one total barrier) will continue to impede access to stream reaches in the study area. The remaining total barrier is on a private road crossing approximately 1 mile downstream of the study area. If this barrier is removed, anadromous salmonids will have improved access to reaches of East Fork Hylebos Tributary in the study area.

Source: WDFW Fish Passage and Diversion Screening Inventory Database (WDFW 2023)

Note:

(1) Barrier slated for correction by WSDOT.

The stream is conveyed under S 336th Street in two parallel, 65-foot-long concrete culverts. One of these has a diameter of 28 inches and the other has a diameter of 18 inches. WDFW (2023) has identified this crossing as a partial barrier to fish passage (Site ID 935274).

Water Quality and Quantity

East Fork Hylebos Tributary is not on the most recent (2018) 303(d) list of impaired waters (Ecology 2023). The nearest listed segment is approximately 2 miles downstream, where East Fork Hylebos Creek is listed as impaired due to elevated levels of fecal coliform bacteria.

East Fork Hylebos Tributary flows intermittently near the Preferred and South 344th Street alternatives. The streambed in this area is typically dry during summer and early fall. The stream channel was completely dry during the October 9, 2019, reconnaissance survey, and a soil pit excavated to a depth of 20 inches below the ground surface elevation in the stream failed to reach the groundwater table. Two weeks later (October 22, 2019), after several days of consistent rainfall, flows were reestablished in the stream channel. In 2022, a notably droughty fall, the stream channel was observed to be dry from August through the second week of October. Several culverted and un-culverted discharges to East Fork Hylebos Tributary were observed during site surveys. On the left bank, a culvert discharges to the stream directly from S 336th Street, which was assumed to be stormwater from the roadway. Another 12-inch-diameter corrugated plastic pipe discharges to the stream along the left bank at Station 1,530 and appears to originate from the adjacent commercial property. A quarry spall-lined channel, originating from a small culvert adjacent to I-5 and presumably conveying stormwater runoff from I-5, enters the right bank at Station 2,042.

Fish and Habitat Use

Current salmonid use of the Hylebos Creek watershed includes fall-run Chinook salmon, fall-run chum salmon, coastal cutthroat trout, odd-year pink salmon, coho salmon, and winter steelhead (HDR 2014; Marks et al. 2018, 2019, 2020, 2021). According to the SWIFD web map, several species of salmon and winter steelhead may potentially be present in East Fork Hylebos Tributary based upon accessible stream gradient (NWIFC 2023). However, there is no documented or presumed[1] salmonid use in East Fork Hylebos Tributary (WDFW 2022; NWIFC 2023). Under current conditions, human-created barriers to fish passage prevent anadromous salmonids from entering stream reaches in the study area (WDFW 2022; NWIFC 2023). No resident salmonids are present given the intermittent flow of the stream, lack of pools with sufficient depth to hold fish during periods when stream channel is dry, and the presence of barriers between the study area and potential population sources downstream. However, resident, non-salmonid species, such as sculpins and sticklebacks, could be present. In addition, the basin size, channel width, and gradient of the stream indicate the potential to support fish in the future. For this reason, the stream is classified as a Type F stream, in accordance with Federal Way Municipal Code section 19.145.260.

The documented distribution of Chinook salmon distribution in the Hylebos Creek watershed does not extend into East Fork Hylebos Creek or its tributaries except for the lowest 730 feet of the stream (WDFW 2022). This is approximately 3 miles downstream of the Preferred and South 344th Street alternatives (WDFW 2022). Chinook salmon are not presumed to use habitats in East Fork Hylebos Creek or its tributaries upstream of that point, but there are no gradient barriers that preclude access to East Fork Hylebos Tributary in the study area (WDFW 2022).

Coho salmon and winter-run steelhead have been documented in East Fork Hylebos Creek approximately 1.85 miles downstream of the Preferred and South 344th Street alternatives (WDFW 2022). Chum salmon have been documented in East Fork Hylebos Creek approximately 2.3 miles downstream of the Preferred and South 344th Street alternatives. Pink salmon have been documented in the lower reaches of Hylebos Creek system and are presumed to occur in East Fork Hylebos Creek as far upstream as 3 miles downstream of the Preferred and South 344th Street alternatives (WDFW 2022; NWIFC 2023). As noted above, the basin size, channel width, and gradient of East Fork Hylebos Tributary in the study area indicate the potential to support these species in the future.

3.1.1.2 West Fork Hylebos Tributary

One surface-flowing segment of West Fork Hylebos Tributary flows through the northwestern corner of the project limits of the Preferred Alternative. An approximately 500-foot-long piped segment of the stream is present at the northern end of the mainline portion of the study area.

West Fork Hylebos Tributary originates on the west side of I-5, near The Commons at Federal Way and Belmor. The stream flows south through residential development to S 336th Street, where it enters a series of stormwater detention ponds. The stream then turns west and crosses

---

[1] Presumed use means reliable documentation of fish use is lacking, but available data and consensus indicate that fish are likely to be present.

SR 99 in a long, piped segment, before joining several other tributaries to form West Hylebos Creek just north of S 356th Street. West Hylebos Creek continues southeast and joins East Fork Hylebos Creek on the east side of I-5 near the Porter Way crossing of I-5. From this point, the stream continues as Hylebos Creek, crossing back across to the west side of I-5 and discharging to the Hylebos Waterway in Tacoma.

Approximately 2,300 linear feet of the stream are within the study area for the Preferred and South 344th Street alternatives. Of that length, less than 400 linear feet flow in open channels and approximately 1,300 linear feet are piped (Figures G3.3-1 and G3.3-2). The remaining 600 linear feet are where the stream lacks a defined channel as it flows through Wetland WFW-02. The stream length in that area is estimated based on linework obtained from the King County iMap interactive mapping tool.

The development history of the area is similar to that of East Fork Hylebos Creek; however, the intensity of development is greater, resulting in higher levels of impervious surface area. With this higher level of development in the basin, West Fork Hylebos has experienced flooding and water quality problems associated with the increased impervious surface area. The city of Federal Way has constructed numerous stormwater facilities across the basin to address the flooding issues, including the stormwater facilities through which West Fork Hylebos Tributary flows near the Preferred Alternative.

Riparian Vegetation

West of the Preferred Alternative, West Fork Hylebos Tributary flows through a stormwater pond north of S 336th Street and enters a second, larger stormwater facility south of S 336th Street. Vegetation within the latter stormwater facility is dominated by native trees and shrubs (Pacific willow, black cottonwood, red-twig dogwood, salmonberry, and Douglas' spiraea) that provide high-quality riparian habitat. This stormwater facility is also mapped as Wetland WFW- 02.

Physical In-Stream Habitat

As noted above, West Fork Hylebos Tributary near the Preferred Alternative is confined within stormwater facilities or pipes. There is no defined channel within Wetland WFW-02. Where it exits the wetland/stormwater facility, the stream flows through a raised outlet standpipe and then enters an approximately 500-foot-long culvert under SR 99. When it is ponded, this facility could retain and support fish use; however, once the facility drains, there is little or no holding water for fish. The pond's substrate is predominantly fine sediment and, as such, provides no suitable spawning habitat for anadromous or resident salmonids.

The surface-flowing segment of West Fork Hylebos Tributary in the mainline portion of the study area is associated with a stormwater facility in Belmor. In contrast to the segment in the Preferred Alternative portion of the study area, the stream's connection to the stormwater facility in Belmor is off-line rather than in-line, which means the stormwater facility has a connection to the stream, but the stream does not flow through the facility.

Biological Connectivity

Numerous barriers to fish passage exist within and downstream of the Preferred and South 344th Street alternative portions of the study area, including seven partial barriers, four total passage barriers, and four crossings that have been assigned an "unknown" barrier status, which means they have been evaluated, but for one reason or another a barrier status could not be assigned. Table G3.3-4 summarizes the status of known fish passage barriers downstream of the Preferred and South 344th Street alternatives.

Table G3.3-4 Fish Passage Barrier Assessment for West Fork Hylebos Tributary Within and Downstream of the Study Area

S 348th Street	933058	Total
S 356th Street	992011	Partial

Source: WDFW Fish Passage and Diversion Screening Inventory Database (WDFW 2023)

The stream is conveyed under S 336th Street in a pair of parallel, 86-foot-long concrete culverts. Both culverts have a diameter of 42 inches. Based on a 2015 field review, WDFW (2023) has identified this crossing as a partial barrier to fish passage.

Water Quality and Quantity

A segment of West Fork Hylebos Tributary approximately 0.2 mile downstream of the Preferred project limits is on the most recent (2018) 303(d) list of impaired waters, based on violations of state standards for copper, lead, zinc, dibenzo(a,h)anthracene, and benzo(a)pyrene (Ecology 2023). Large amounts of impervious surface area in the upper watershed have likely contributed to elevated levels of pollutants associated with vehicle use, including metals such as copper, lead, and zinc.

The high level of development and associated impervious surface in the West Fork Hylebos Creek basin have resulted in severe flooding issues over the years and have contributed to altered peak and base flows in West Fork Hylebos Tributary (King County 1990). As a result, Federal Way has initiated and completed numerous flood control projects, including large stormwater facilities throughout the basin.

Fish and Habitat Use

The SWIFD web map shows no salmonid fish present in West Fork Hylebos Tributary (NWIFC 2023). Based on the presence of human-created barriers to fish passage, no anadromous fish are documented or presumed to use West Fork Hylebos Tributary in the Preferred and South 344th Street alternatives portions of the study area (WDFW 2022; NWIFC

2023). No resident salmonids are present, given the intermittent flow of the stream, lack of pools with sufficient depth to hold fish during periods when stream channel is dry, and the presence of barriers between the study area and potential population sources downstream. However, resident, non-salmonid species, such as sculpins and sticklebacks, could be present. In addition, the basin size, channel width, and gradient of the stream indicate the potential to support fish in the future. For this reason, the stream is classified as a Type F stream, in accordance with Federal Way Municipal Code section 19.145.260.

The documented distribution of Chinook salmon in the Hylebos Creek watershed extends into the lower reaches West Fork Hylebos Creek (NWIFC 2023). The upstream limit of documented Chinook salmon presence mapped by NWIFC (2023) is near S 373rd Street, approximately 2.9 miles downstream of the Preferred Alternative. However, fisheries biologists from the Puyallup Tribe of Indians have observed Chinook salmon in West Fork Hylebos Creek as far upstream as S 356th Street, another 1.4 miles farther upstream (Marks et al. 2018, 2019, 2020, 2021). Chinook salmon are not known or presumed to use habitats in West Fork Hylebos Creek or its tributaries upstream of that point, but there are no gradient barriers that would preclude access to West Fork Hylebos Tributary in the study area if human-created barriers are removed (WDFW 2019b).

The Puyallup Tribal Fisheries Department has documented chum salmon, coho salmon, pink salmon, and steelhead spawning in reaches of West Fork Hylebos Creek approximately 2.2 miles downstream of the study area for the Preferred Alternative (Marks et al. 2018, 2019, 2020, 2021). According to NWIFC (2023), reaches of West Fork Hylebos Creek 1.5 miles downstream of the Preferred Alternative support spawning by coho salmon. Other fish species documented in West Fork Hylebos Creek include threespine stickleback, western brook lamprey, yellow perch, bass and sculpin (HDR 2014; Marks et al. 2018, 2019, 2020, 2021). As noted above, the basin size, channel width, and gradient of West Fork Hylebos Tributary in the study area indicate the potential to support these species in the future.

Based on habitat conditions, bull trout are not expected to use stream habitats in the Hylebos Creek watershed. Bull trout are strongly associated with snowmelt-dominated streams that maintain cold water temperatures in headwater tributaries year-round. Streams in the Hylebos Creek watershed are rainfall-dominated. In addition, stream temperatures are regularly higher than the temperatures this species requires. Despite these conditions, a single sub-adult bull trout was captured near the S 373rd Street crossing of West Fork Hylebos Creek in August 2018, approximately 4 miles downstream from the study area of the Preferred Alternative. For this analysis, it is assumed that individual bull trout could venture into accessible segments of Hylebos Creek and its tributaries in the future. The presence of any such fish would likely be brief based on the lack of high-quality habitat for bull trout in those streams.

3.1.1.3 North Fork McSorley Creek

North Fork McSorley Creek is included in the Lower Puget Sound–Des Moines/Federal Way drainage basin of WRIA 9 and originates in Des Moines, approximately 2,000 feet west of the Midway Landfill Alternative. The headwaters of North Fork McSorley Creek are near Parkside Elementary School west of SR 99. From there, the stream flows west and then south-southwest through primarily single-family residential areas before entering Saltwater State Park on the west side of 16th Avenue S. At that point, the stream joins South Fork McSorley Creek to form McSorley Creek, continuing west to its discharge point in Puget Sound. The stream length from the headwaters to McSorley Creek’s discharge point into Puget Sound is approximately 1.8 miles. The portion of stream within the residential areas has been highly modified and confined to a straight and narrow ditch-like feature with a limited riparian corridor.

While no surface-flowing portions of North Fork McSorley Creek are within the Midway Landfill Alternative study area, a regional stormwater detention facility at the north end of the study area discharges to North Fork McSorley Creek approximately 1.1 miles west of the study area at the S 250th Street stream crossing. Figure G3.3-3 shows the pipe discharging from the stormwater detention facility. This pipe conveys only stormwater; it is not part of the stream network. Limited information is provided below to describe what is known about existing water quality and fish use of North Fork McSorley Creek, because these are the elements that could potentially be affected by any stormwater discharges from the Midway Landfill Alternative to the regional stormwater facility.

Biological Connectivity

Numerous barriers to fish passage exist downstream of the Midway Landfill Alternative study area, including one culvert on a non-fish-bearing segment of stream, three total fish passage barriers, and four partial barriers. Table G3.3-5 summarizes the status of known fish passage barriers on North Fork McSorley Creek downstream of the Midway Landfill Alternative.

Table G3.3-5 Fish Passage Barrier Assessment for North Fork McSorley Creek

Approximate Road Crossing	Unique Site ID	Barrier Status
Parkside Elementary School	940301	On a non-fish-bearing stream
20th Avenue S	940300	Total
S 245th Place	940299	Partial
S 246th Place	940298	Partial
Outlet of Martindale Lake	940296	Total
S 250th Street	940295	Total
Private Property	940294	Partial
Saltwater State Park	940284	Partial

Source: WDFW Fish Passage and Diversion Screening Inventory Database (WDFW 2023)

Water Quality and Quantity

North Fork McSorley Creek is not listed on the Ecology 303(d) list of impaired waterbodies for any parameters. The nearest listed stream segment is McSorley Creek, approximately 1.2 miles from the Midway Landfill Alternative. McSorley Creek contains 303(d) listings for bacteria and dissolved oxygen (Ecology 2023).

No hydrologic data are available for North Fork McSorley Creek; however, the stream is known to have intermittent or seasonal flow between the headwater area at Parkside Elementary School and Martindale Lake just upstream of S 250th Street.

Fish and Habitat Use

Electrofishing surveys conducted by Washington Trout (2003) documented the presence of coastal cutthroat trout in North Fork McSorley Creek as far upstream as S 250th Street (approximately 1 mile from the study area) and western brook lamprey as far upstream as 20th Avenue S (a total barrier to fish passage approximately 0.5 mile west of the study area). Washington Trout also found juvenile chum salmon, juvenile coho salmon, juvenile rainbow trout/steelhead, sculpin, and sea-run and resident cutthroat trout in the lower reaches of the main stem of McSorley Creek.

According to NWIFC (2023), fall-run Chinook salmon, fall-run chum salmon, coho salmon, and winter-run steelhead are potentially present[2] in North Fork McSorley Creek as far upstream as Martindale Lake, approximately 1 mile west of the study area. With the exception of the potential presence of Chinook salmon, these determinations of potential presence are all superseded by the documented observations of the Washington Trout survey (2003).

3.1.2 Aquatic Species of Concern

3.1.2.1 ESA-listed Species and Critical Habitat

Discussions in this document pay particular attention to species with listing status under the ESA because such status triggers additional regulatory review. The ESA requires each federal agency to ensure that any actions it undertakes or approves do not jeopardize the continued existence of endangered or threatened species or result in the destruction or adverse modification of their designated critical habitat. For this project, federal approval would be required for construction and operation of OMF South facilities in the I-5 right-of-way. To meet this requirement, a lead federal agency would evaluate the potential impacts of the project selected by the Sound Transit Board of Directors on ESA-listed species and critical habitat and, if necessary, initiate consultation with USFWS and NMFS. The assessment would also include a review of potential effects on Essential Fish Habitat, as required by the Magnuson-Stevens Fishery Conservation and Management Act.

Aquatic species that are currently protected under the ESA and that have the potential to occur in the study area include Chinook salmon and steelhead, which are listed as threatened. In addition, the USFWS Information for Planning and Consultation planning tool identified bull trout (another regionally important and federally threatened species) as potentially occurring in areas that might be affected by the project. As discussed above, it is possible, albeit unlikely, that individual bull trout could venture into accessible segments of Hylebos Creek and its tributaries in the future. Numerous barriers to fish passage, combined with small stream sizes and intermittent flow regimes, prevent any of these species from entering stream reaches in the study area. The distribution of these species within affected waterbodies is discussed in more detail above in Section 3.1.1, Streams in the Study Area.

None of the stream reaches in the study area includes any proposed or designated critical habitat for ESA-listed species. However, historically accessible reaches of these streams are designated as Essential Fish Habitat for Pacific salmon, triggering consultation requirements under the Magnuson-Stevens Fishery Conservation and Management Act.

Critical habitat has been designated for Chinook salmon and steelhead within the Hylebos Creek watershed, but not East Fork Hylebos Tributary or West Fork Hylebos Tributary. With respect to East Fork Hylebos Creek and Preferred and South 344th Street alternatives, the nearest designated critical habitat for Chinook salmon is approximately 3 miles downstream of the study area, and the nearest designated critical habitat for steelhead is approximately 1.85 miles downstream of the study area. With respect to West Fork Hylebos Creek and the Preferred Alternative, the nearest designated critical habitat for Chinook salmon is approximately 2.5 miles downstream of the study area, and the nearest designated critical habitat for steelhead is approximately 1.6 miles downstream. Critical habitat has not been designated for any aquatic species in McSorley Creek or North Fork McSorley Creek with respect to the Midway Landfill Alternative.

---

[2] Fish are classified as potentially present in a stream segment if artificial obstructions, degraded habitat quality, or extirpation of local populations currently preclude their presence, but the stream segment has the potential to support these species if obstructions were removed, habitat restored, and/or fish reintroduced (WDFW 2022c).

Critical habitat for bull trout is not present within any of the stream reaches in the study area; however, bull trout critical habitat has been designated along the marine nearshore of Puget Sound at the mouths of both Hylebos Creek and McSorley Creek and includes the upstream extent of tidal influence into both streams.

3.1.2.2 Other Aquatic Species of Concern

Currently, no state-listed fish species are expected to occur in streams within the study area. Resident coastal cutthroat trout, identified as a state priority species due to its recreational importance, has not been documented as occurring in either East Fork Hylebos Tributary or West Fork Hylebos Tributary. However, there is a potential for this species to occur in these streams downstream of the study area. It is possible that remnant populations have persisted in these streams after the barriers were installed, but the potential is very low given the presence of numerous barriers on the system, seasonal flow, and lack of pools with adequate holding depth to remain wetted over the drier summer months. Presence within North Fork McSorley Creek and the Midway Landfill Alternative is not anticipated. The cities of Kent and Federal Way have not identified any species of local concern at this time.

3.2 Vegetation, Wildlife, and Wildlife Habitat

The study area includes a variety of cover types and wildlife habitats. Much of the study area is dominated by urban development, including industrial, institutional, commercial, and residential areas. These areas support plant and animal species adapted to disturbed urban areas. However, patches of less-developed habitats occur along the Hylebos Creek tributaries in Federal Way and at the Midway Landfill in Kent. Vegetation conditions and wildlife habitats are described in the following subsections, followed by a summary of species and habitats of concern that are known or expected to be present in the study area.

3.2.1 Vegetation

Vegetation in the study area was classified in land cover types and characterized according to the methods described in Section 2.2.2, Methods. Ten cover types were identified in the study area: commercial, residential, grassland, invasive brush, native brush, non-native forest, mature native forest, other native forest, wetland/stream, and stormwater pond. Table G3.3-6 lists these cover types and summarizes the acreage of each. Because the footprints of the two project alternatives in Federal Way overlap substantially, land cover acreage values for the portion of the study area surrounding those two sites (including lead tracks) are presented together. Similarly, land cover acreage values for the mainline track options are presented together. Figures G3.3-4, G3.3-5, and G3.3-6 depict the distribution of the cover types in the study area around the project alternatives. The figures also depict priority habitats that have been identified and mapped by WDFW. Representative photographs of each cover type are included in Attachment G3-6.

The following subsections describe and summarize the relative habitat value of the land cover types in the study area. Relative habitat value is based on habitat structure, scarcity in the study area, disturbance types and frequency, and time required for ecosystem functions to recover following clearing and replanting. Priority habitats, based on WDFW definitions (WDFW 2008) are identified and described in Section 3.2.3, Species and Habitats of Concern.

Table G3.3-6 Vegetation and Wildlife Habitats in the OMF South Study Area

Land Cover Type	Acres in Study Area			
	Preferred and South 344th Street Alternatives	Mainline	Midway Landfill	Total

FIGURE G3.3-6
Vegetation Cover Existing Conditions
Midway Landfill Alternative

OMF South

3.2.1.1 Commercial

The commercial cover type represents the heavily developed and built portions of the study area. It includes large buildings and parking lots, most of which are commercial areas. These areas contain minimal habitat value for wildlife. Vegetation is restricted to scattered non-native trees in landscaping, and invasive species. These features could provide some habitat for species adapted to disturbed and developed conditions (e.g., house sparrows, American robins, European starlings, American crows). Dominant species within commercial areas within the study area are non-native trees and shrubs, including horticultural species and invasive species, such as Himalayan blackberry.

This cover type has a relatively low value for wildlife. If disturbed during construction, there would be minimal effects on existing vegetation or wildlife habitat. The minimal habitat present could be easily replaced following construction. The built portions of the proposed project would have similar vegetation condition and habitat value compared to current conditions.

3.2.1.2 Residential

The residential cover type represents developed areas with houses, driveways, yards, and associated landscaping. Vegetation includes mown lawns, horticultural species, and native species in some areas. Regular disturbances from humans and domestic animals limit habitat value for some wildlife species. However, the higher cover and diversity of vegetation provides some habitat value, compared to fully developed and built commercial areas. Relative habitat value is low.

If disturbed during construction, there would be effects on existing vegetation and wildlife habitat. The habitat present could be replaced following construction as landscaped elements of OMF South. However, the configuration of the habitat and overall cover may change compared to current conditions, based on the design.

3.2.1.3 Grassland

The grassland cover type represents areas dominated by upland grasses and other herbaceous species. They are maintained in the study area through mowing and brush control. The largest patch of this habitat occurs at the Midway Landfill. Large patches of grassland are relatively rare in the vicinity of the study area and restricted to large landholdings. Wildlife species associated with grassland habitats in the study area include Savannah sparrows, barn swallows, swallowtail butterflies, meadow voles, and Townsend’s moles. Red-tailed hawks and other raptors prey on voles and other small mammals that are found in abundance in grassy habitats. Relative habitat value is moderate.

If disturbed during construction, the habitat present could be easily replaced following construction, as the establishment of grasses could occur within weeks following construction.

Dominant species within the study area surrounding the Preferred and South 344th Street alternatives are fescues, velvetgrass, and bluegrass. Dominant species within the Midway Landfill study area were bentgrass, bluegrass, fescues, Bermuda grass, and other non-native grass and herbaceous species.

3.2.1.4 Invasive Brush

The invasive brush land cover type represents areas dominated by non-native brush species such as Himalayan blackberry, Scotch broom, and butterfly bush. Although non-native, this habitat does provide nesting, foraging, and refuge habitat for several species of birds and small mammals.

If disturbed during construction, the habitat present could be easily replaced and restored following construction. Temporarily disturbed areas would be restored with native plants suitable to the site, and/or horticultural species in landscaped areas. Re-establishment of native and non-native brush species is expected to be rapid (within a year). Relative habitat value is low.

3.2.1.5 Native Brush

The native brush cover type represents areas dominated by native species that include shrub species and/or sapling-sized tree species. Typical species observed in the study area include Nootka rose, sweet gale, salmonberry, black cottonwood, and red alder. This habitat provides nesting, foraging, and refuge habitat for birds and small mammals, as well as native species resources for the wildlife food web, including pollinators. Overall habitat value is moderate; it provides good habitat for native species and is able to reestablish quickly following disturbances.

3.2.1.6 Non-Native Forest

Forests composed primarily of non-native species occur in the study area. Although most of these non-native forests represent plantings of horticultural species as part of residential or commercial development, some areas have been colonized by non-native species. The planted areas are dominated by Austrian pine, Norway maple, and Lombardy poplar. Areas colonized by non-native trees are dominated by honey locust, European mountain ash, and bird cherry.

These forests, though non-native, do provide some habitat value for local wildlife, as well as stormwater moderation and other ecosystem functions. If removed as part of this project, these functions would be temporarily lost, and the recovery of these functions would take years to decades (time for the trees to mature). Given the vigorous nature of these species, however, it would not be difficult to reestablish these plant communities given time. Relative habitat value is moderate.

3.2.1.7 Mature Native Forest

Some of the upland forested areas in the study area meet WDFW’s criteria for the Mature Forest priority habitat type. These stands are generally over 80 years old, with trees exceeding 21 inches in diameter at breast height, on average (WDFW 2008). These forests are dominated by Douglas-fir, western redcedar, western hemlock, and black cottonwood. The understory in many areas is dominated by native shrubs and groundcovers, although English ivy, Himalayan blackberry, and other weeds have encroached on some areas.

Compared to other cover types, structurally complex habitats, such as native forested areas and wetlands, have more biological diversity and higher value as wildlife habitat. With habitat features such as large trees, snags, decaying logs, and a diverse understory, areas classified as Mature Native Forest typically support diverse communities of forest-associated wildlife. Because of the long time period (decades to centuries) needed to reestablish native forested conditions, disturbance or removal of this habitat type would have a substantial effect on habitat throughout the time period needed to reestablish the forests.

3.2.1.8 Other Native Forest

The other native forest land cover type represents forests dominated by native tree species but lacking the defining features of mature forest (see Section 3.2.1.7, Mature Native Forest, above). Several types of native forests (coniferous, deciduous, and mixed) were observed in the study area. Relative habitat value is high.

Coniferous forests in the study area are dominated primarily by Douglas-fir and western redcedar, with occasional occurrences of Sitka spruce and shore pine. Deciduous forests are dominated by black cottonwood and red alder, with some occurrence of bigleaf maple, bitter cherry, and the broad-leaved evergreen tree, Pacific madrone. Mixed forests are dominated by a combination of the species described above. Forests with native understory commonly contain sword fern, salal, osoberry, beaked hazelnut, and red elderberry. Forests with an invasive understory typically contain Himalayan blackberry, cut-leaf blackberry, butterfly bush, and English ivy.

Dominant species within the study area surrounding the Preferred and South 344th Street alternatives are Douglas-fir, western redcedar, western hemlock, and black cottonwood. Dominant species within the Midway Landfill Alternative study area are bigleaf maple, red alder, black cottonwood, and madrone.

All native forest areas provide high habitat value for native wildlife, based on the diversity and structural complexity provided by overstory trees and understory shrubs. Many areas classified as other native forest are several decades old and would require several decades to recover following disturbance. For these reasons, the other native forest cover type is considered to have a high habitat value.

3.2.1.9 Wetland/Stream

The wetland/stream land cover type represents areas with high water tables, including stream channels, wetlands, and frequently flooded areas. In the study area, streams and wetlands are interwoven into complexes of vegetated wetlands, scoured channels, and vegetated areas within the OHWL of streams. Areas classified as wetland/stream provide habitat functions similar to those described above for forests, brush areas, and grasslands (i.e., nesting, perching, hiding, and foraging habitats for many species), but with added habitat value due to the presence of water and unique habitats for water-dependent species, such as fish and amphibians. Relative habitat value is high. The existing conditions and habitat values of individual wetlands and streams are described previously in Sections 3.1, Aquatic Species and Habitat, and 3.2, Vegetation, Wildlife, and Wildlife Habitat. Habitat value is discussed by wetland.

Forested areas associated with wetlands and streams in the study area are dominated by Pacific willow, red alder, Oregon ash, and black cottonwood, with an understory of Douglas' spiraea, salmonberry, Himalayan blackberry, slough sedge, and reed canarygrass. Similar to the forests described in the section above, the removal or disturbance of forested areas associated with wetlands would take years to decades to recover temporarily lost habitat functions.

Scrub-shrub areas associated with wetlands and streams in the study area are dominated by Scouler's willow, salmonberry, Himalayan blackberry, red-twig dogwood, and Douglas' spiraea. Re-establishment of scrub-shrub vegetation can be rapid after disturbances (within a few years), but often slower than emergent systems (within a year).

Emergent areas associated with wetlands and streams in the study area are dominated by reed canarygrass, bulrushes, beggar ticks, and smartweeds. Re-establishment of emergent vegetation can be rapid after disturbances.

3.2.1.10 Stormwater Pond

The stormwater ponds support native and non-native wetland species adapted to fluctuating water tables and disturbances related to maintenance. Common species in the stormwater ponds are reed canarygrass, cattails, bulrushes, and willows. Areas of open water in constructed stormwater ponds provide resting and foraging areas for birds such as waterfowl and great blue herons. Due to extreme water level fluctuations and regular disturbance for maintenance, the relative habitat value of this cover type is low. Stormwater ponds that are designed to rapidly fill with water and hold water only for a short period following precipitation events (as a way of maximizing groundwater recharge or minimizing mosquito populations) can attract amphibians and other aquatic species and then compromise embryonic and larval survival when the pond dries or water elevation rapidly increases. Regular maintenance, including removal of vegetation and accumulated sediments, further reduces habitat value by altering habitat structure, soils, and in-water conditions.

3.2.1.11 Priority Habitats

In addition to the priority areas mapped by WDFW (see Section 3.2.3, Species and Habitats of Concern), some portions of the study area meet the criteria established by WDFW for Priority Habitats. The streams in the study area and the vegetated areas along the streams are Riparian priority habitats. Approximately 13 acres of the upland forested habitat in the study area meet the criteria for Mature Forest priority areas. Streams are shown in Figures G3.3-1, G3.3-2, and G3.3-3. Areas of Mature Forest are shown in Figures G3.3-4 and G3.3-5.

3.2.2 Terrestrial Wildlife

Wildlife use of habitats in urban landscapes depends on the general location of the habitat, the size and type of undisturbed habitats, the degree of connectivity and extent of travel corridors between and among these habitats, and the types and levels of human activity. Much of the study area falls within commercial, industrial, institutional, and residential areas that provide habitat only for adaptable species, such as house sparrows, European starlings, rats, mice, raccoons, Virginia opossums, and eastern gray squirrels. Birds, such as rock pigeons and cliff swallows, commonly build nests on bridges and road overpasses, and many bat species use such structures as temporary roosting sites. Animals that use habitats in the study area are also exposed to high levels of disturbance generated by human activity in commercial and industrial areas and by traffic on I-5 and major arterial roadways.

Most patches of forest cover in the study area are fragmented and separated from surrounding habitat areas by commercial and residential developments and roads. Despite their isolation, these areas still provide habitat for forest-associated resident and migratory songbirds, as well as for hawks, owls, woodpeckers, and small mammals. The largest patch of forested habitat in the study area, approximately 10 acres, is adjacent to I-5, along the eastern boundary of the Preferred and South 344th Street alternatives. As indicated by the detection of an ensatina (a terrestrial salamander whose eggs develop directly into adults without an aquatic larval stage, a reproductive strategy that depends on cool and humid conditions) during a site visit in October 2019, this patch supports many ecosystem functions, despite its isolation from other, less-disturbed areas of forest habitat.

Larger habitat patches and those connected to other natural areas or heavily vegetated residential neighborhoods support a larger variety of species, such as songbirds, raptors, small mammals, coyotes, and black-tailed deer. Songbird species commonly found in habitats similar to those in the study area include American robin, song sparrow, Steller's jay, American crow, spotted towhee, black-capped chickadee, white-crowned sparrow, northern flicker, Bewick's wren, and red-breasted nuthatch. Raptors include American kestrel, sharp-shinned hawk, Cooper's hawk, red-tailed hawk, and great horned owl. Red-tailed hawks and other raptors prey on voles and other small mammals that are found in abundance in the grassy vegetation at Midway Landfill and in the I-5 right-of-way. A northern harrier was observed near the stormwater detention pond at the Midway Landfill site in October 2019. Open-water habitats, such as wetlands and stormwater detention ponds, provide resting and foraging areas for waterfowl.

Structurally complex habitats, such as forested areas and wetlands, generally have comparatively high levels of biological diversity and value as wildlife habitat. With habitat features such as large trees, snags, decaying logs, and a diverse understory, areas classified as mature native forest typically support diverse communities of forest-associated wildlife.

Streams and riparian areas are used as travel corridors by many wildlife species. Despite the widespread urbanization of the study area, riparian areas along streams may serve as a connective corridor between pockets of wildlife habitat. In general, however, patches of forest and other native habitat types in the study area are isolated from other areas of similar habitat and do not serve as connective corridors to other areas of habitat outside of the study area. I-5 impedes the movement of wildlife between the Green River valley in the east and the Puget Sound shoreline to the west.

3.2.3 Species and Habitats of Concern

The Natural Heritage Program database does not include any records of extant rare plant populations or high-quality ecosystems in the study area (WDNR 2019). The only such record within 5 miles of the project alternatives is a population of Canadian St. John's-wort, a state sensitive species. It is mapped east of I-5 and approximately 0.6 mile southeast of the South 344th Street Alternative. The only high-quality ecosystems identified within 5 miles of the project alternatives are a bog identified by WSDOT east of I-5 and just north of S 320th Street and a forested bog in West Hylebos Wetlands Park, approximately 0.5 mile southwest of the South 344th Street Alternative. No rare plant species or high-quality ecosystems (as defined by the Natural Heritage Program) were observed in the study area during field surveys.

WDFW (2022) does not identify any occurrences of priority wildlife species within 0.25 mile of any of the project alternatives. The only mapped priority habitats within or near the study area are wetland areas (WDFW 2022). Wetlands are discussed in Section 3.3. Riparian areas, another WDFW priority habitat type, occur adjacent to surface-flowing streams in the study area but are not mapped by WDFW. The condition of riparian habitats in the study area is described in Section 3.1.1, Streams in the Study Area. Mature forest, meeting the definition of state priority habitat, was also identified in the field as shown on Figures G3.3-4 and G3.3-5.

Historically, King County (1991) identified regionally and locally important resource areas in the drainage basins that include the study area. Important resource areas are subcatchments, wetlands, or stream reaches that are important to the viability, diversity, and abundance of fish and wildlife populations. No such areas were identified in the study area (King County 1991).

Based on field observations, literature review, and sightings databases (e.g., eBird 2022; Opperman et al. 2006; Seattle Audubon Society 2022; WDFW 2022), biologists identified wildlife species of concern that may use habitats in the study area (i.e., non-marine habitats in lowland urban and residential settings, excluding unique habitats that are not found in the study area, such as old-growth forest or sphagnum bogs). Table G3.3-7 lists these species and summarizes each species' known or expected use of habitats in the study area. No wildlife species of concern were observed in the study area during field surveys conducted for this project.

No wildlife species that are listed or proposed for listing under the ESA are known or expected to use habitats in the study area. For this reason, based on the definition of species of concern in Section 2.2.2, Methods, the only species of concern identified in Table G3.3-7 are state priority species (including one state-listed sensitive species, the common loon). Table G3.3-7 also lists the priority areas that have been identified by WDFW for each of these species. In many cases, WDFW considers species to be a priority only within known limiting habitats (e.g., breeding areas) or within areas that support a relatively high number of individuals (e.g., regular concentrations). For example, great blue herons are often found feeding along shorelines, but they are considered a priority only in breeding areas (WDFW 2008).

Table G3.3-7 Wildlife Species of Concern Potentially Occurring within the Study Area

Species[1]	Priority area(s)	Known or Expected Habitat Use in the Study Area
Amphibians		
Western toad	Any occurrence	No recent records near the study area. May breed in permanent wetlands, ponds, lakes, and off-channel habitats or rivers; adults may move through uplands for several miles.
Birds		
Band-tailed pigeon	Regular concentrations, occupied mineral sites	Observed in suitable habitat near the study area year-round, but no regular concentrations or mineral springs have been recorded. May nest in trees, commonly in tall conifers near open sites.
Barrow's goldeneye	Breeding areas	No known observations in the study area. Occasionally seen on larger waterbodies nearby (e.g., Lake Killarney), primarily during winter. Not expected to breed in or near the study area.
Brant	Regular concentrations in foraging and resting areas, migratory stopovers	No known observations in the study area. The study area is not expected to provide migratory stopover sites or foraging or resting areas.
Common goldeneye	Breeding areas	No known observations in the study area. Occasionally seen on larger waterbodies nearby, primarily during winter. Not expected to breed in or near the study area.
Common loon	Breeding sites, migratory stopovers, regular concentrations	No known observations in the study area. No suitable breeding sites (large lakes with low disturbance levels) in or near the study area. The study area is not expected to provide migratory stopover sites.
Great blue heron	Breeding areas	Observed in suitable habitats near the study area year-round. Nests in mature forests, forages in shallow, slow-moving, or still water. No known breeding sites within 1 mile of any site alternatives.
Hooded merganser	Breeding areas	Observed in suitable habitats near the study area year-round. May nest in tree cavities near small, forested, freshwater wetlands with emergent vegetation.
Oregon vesper sparrow	Any occurrence	Associated with open habitats. Breeding population in Washington is largely limited to remnant prairies and grasslands in Pierce, Thurston, and Skagit counties. Rarely observed in southwestern King County during migration periods.
Pileated woodpecker	Breeding areas	Occasionally seen, year-round; breeding possible. Requires forested habitats with large trees and snags. No evidence of presence in forested area near Preferred Alternative site.

Table G3.3-7 Wildlife Species of Concern in the Study Area (continued)

Species[1]	Priority area(s)	Known or Expected Habitat Use in the Study Area
Trumpeter swan	Regular concentrations	No known observations in the study area. Occasionally seen on larger waterbodies nearby, primarily during winter. The study area is not expected to support concentrations.
Tundra swan	Regular concentrations	No known observations in the study area. Occasionally seen on larger waterbodies nearby, primarily during winter. The study area is not expected to support concentrations.
Vaux's swift	Breeding areas, communal roosts	Observed in suitable habitat near the study area, primarily during the breeding season. Nests and roosts in natural cavities with vertical entranceways, such as hollow trees and snags, in areas of coniferous or mixed forest.
Western grebe	Breeding areas, regular concentrations, migratory stopovers, regular occurrences in winter	Occasionally seen near open water, generally outside of the breeding season. Not expected to breed in or near the study area. The study area is not expected to provide migratory stopover sites or support concentrations.
Wood duck	Breeding areas	Observed in suitable habitats near the study area year-round. May nest in tree cavities near wooded wetlands.
Mammals		
Big brown bat, *Myotis* bats	Regular concentrations in naturally occurring breeding areas and other communal roosts	No known maternity or hibernation colonies or other concentrations in or near the study area. Summer roosts generally are in buildings, bridges, hollow trees, spaces behind exfoliating bark, rock crevices, or tunnels. Maternity colonies may form in attics, barns, rock crevices, or tree cavities. Caves, mines, and buildings are used for hibernation.
Townsend's big-eared bat	Any occurrence	No known maternity or hibernation colonies or other concentrations in or near the study area. Maternity and hibernation colonies typically are in caves, mine tunnels, and old buildings. Caves, tunnels, buildings, and tree cavities are used as night roosts.

Sources: eBird 2022; Opperman et al. 2006; Seattle Audubon Society 2022; WDFW 2008, 2022.

Note:

(1) All species in this table are State priority species; the common loon is a state sensitive species as well. No wildlife species listed or proposed for listing under the ESA are known or expected to use habitats in the study area.

Forested areas in the study area could provide suitable habitat for the following priority species: band-tailed pigeon, pileated woodpecker, Vaux's swift, big brown bat, *Myotis* bats, and Townsend's big-eared bat. Hooded mergansers and wood ducks may nest in forested wetlands. Open, grassy habitats at Midway Landfill may provide suitable habitat for migrating Oregon vesper sparrows.

The USFWS Information for Planning and Consultation planning tool identified five ESA-listed wildlife species, and one species proposed for listing, as potentially occurring in areas that might be affected by the project. None of these species is expected to occur in the study area, however, for the following reasons:

- Marbled murrelets, listed as threatened, require old-growth forest for nesting and marine habitat for foraging. No breeding or foraging habitat is present in the study area and no observations have been documented within 10 miles (WDFW 2022). The nearest location where critical habitat has been designated for the marbled murrelet is more than 25 miles from the study area.
- Yellow-billed cuckoos, listed as threatened, require large blocks of riparian forest habitat for breeding and foraging. Yellow-billed cuckoos nest almost exclusively in low- to mid-elevation riparian woodlands that cover 50 acres or more (Hughes 1999). No such habitat is present in or near the study area. Currently, the species no longer breeds in western Canada or the

northwestern continental United States (Washington, Oregon, and Montana) (79 FR 59992, October 3, 2014). No observations of this species have been documented within 10 miles of the study area (WDFW 2022). No critical habitat for the yellow-billed cuckoo has been proposed in Washington.

- Streaked horned larks, listed as threatened, are known to occur in Washington only in portions of southern Puget Sound, along the Washington coast, and at lower Columbia River islands (78 FR 61452, October 3, 2013). Breeding habitat for streaked horned larks in Washington consists of grasslands and sparsely vegetated areas at airports, sandy islands, and coastal spits. The subspecies is largely absent from the Puget Trough during the nonbreeding season; individuals observed in this area outside of the breeding season have been seen using habitats similar to those used for breeding. The only potential suitable habitat for streaked horned larks in the study area is at the Midway Landfill site, which includes about 60 acres of grassy land cover. The likelihood that streaked horned larks use the Midway Landfill site is minimal, however, due to the site’s size, distance from occupied sites, and scarcity of bare-ground habitat. Sites used by larks typically encompass hundreds of acres, but larks may use smaller sites that are located relatively close to occupied sites and/or along rivers (Anderson and Pearson 2015). The smallest site with evidence of streaked horned lark use in the Puget Trough region is 90 acres (Anderson and Pearson 2015). While the approximately 60acre Midway Landfill site is substantially smaller than 90 acres, the adjacent I-5 corridor may create a visual impression similar to that of a river, potentially increasing the site’s size, as perceived by larks. However, the nearest occupied site is more than 15 miles away (WDFW 2022). In addition, the Midway Landfill site is dominated by densely growing sod-forming grasses (although a few scattered patches of bare ground are present along access roads). Streaked horned larks typically select habitat patches with low, sparse vegetation and a relatively high percent cover of bare ground, avoiding areas dominated by shrubs or sod-forming grasses (Anderson and Pearson 2015). Streaked horned larks have not been documented at the landfill or in surveys at Seattle-Tacoma International Airport north of the action area, and their presence in the action area is unlikely (Sound Transit 2016a). The nearest designated critical habitat for the streaked horned lark is more than 100 miles from the study area.
- Taylor’s checkerspot butterflies, listed as endangered, require grassland dominated by fescue or other short-stature grass species, with a diversity of larval host plants and spring nectar sources (Stinson 2005). The nearest known population is more than 15 miles from the project area. Populations in the Puget Sound region are primarily associated with shallow-soil balds and grasses within forested landscapes. In Washington and Oregon, Taylor’s checkerspot butterfly larvae feed primarily on native paintbrush and closely related species (e.g., *Castilleja hispida*, *C. levisecta*, *Tryphasaria* spp.), and on plantain species such as non-native *Plantago lanceolata* and native *Plantago maritima* (61938 FR 77, October 11, 2012). Other annuals documented as larval host foods include several species of speedwell (*Veronica* spp.), blue-eyed Mary (*Collinsia grandiflora* and *C. parviflora*), and sea blush (*Plectritis congesta*). *Plantago lanceolata* and *Plantago maritima* could be present at Midway Landfill and in other areas dominated by low-stature plants. Other larval host species have not been observed and are unlikely to be present. Grosboll (2011) found that, within areas of broadly suitable grassland vegetation structure, Taylor’s checkerspot butterfly adults lay their eggs in the areas with very high densities of host plants. Of 31 oviposition locations studied, the volume of host plants in all but one exceeded 10,000 cubic centimeters per square meter. No areas with such high densities of paintbrush or plantain species have been observed in the study area.

- North American wolverines, listed as threatened, avoid people and developed areas and prefer cold and remote mountainous areas with persistent spring snow cover. No such habitat is present in the lowland, urban setting of the study area.
- Northwestern Pond Turtle, proposed for listing as threatened, occurs at only six locations in the state, including three sites in Skamania County, and one each in Klickitat, Mason, and Pierce counties (Hallock et al. 2017). In Washington, they are found associated with ponds, small lakes, and wetlands at elevations below 300 m (985 ft.) (Hays et al. 1999). The closest population is over 10 miles from any of the alternatives. In addition to small population size and distance to known populations, the developed nature of the project areas and dense road networks limit the potential for presence of the species; the potential for the species to occupy habitats in the study area without human intervention is extremely unlikely.

The list provided by USFWS does not identify the gray wolf as an ESA-listed species potentially present in the action area. This may be a product of the rule issued by USFWS on November 3, 2020 (85 Federal Register [FR] 69778), removing gray wolves from the list of species protected under the ESA. However, on February 10, 2022, the U.S. District Court for the Northern District of California vacated and remanded USFWS' delisting rule. The court's decision effectively reinstated the listing status the species had before USFWS issued the delisting rule. As a result, gray wolves in western Washington have a listing status of endangered. Gray wolves require habitats with high prey densities and low levels of human disturbance. No such habitat is present in the lowland, urban setting of the project area. Critical habitat for the gray wolf has not been proposed for designation in Washington State.

The Migratory Bird Treaty Act of 1918, administered by USFWS, makes it unlawful to take any migratory bird, or the parts, nests, or eggs of any such bird, except under the terms of a valid permit. In the context of this Act, 'take' is defined as, "pursue, hunt, shoot, capture, collect, kill, or attempt to pursue, hunt, shoot, capture, collect, or kill" (16 U.S. Code § 715n). Nearly all bird species that may occur in the study area are protected under the Migratory Bird Treaty Act. Birds or bird nests protected under the Act may be present in any of the cover types described in Section 3.2.1, Vegetation. Forested areas, wetlands, and other areas with comparatively complex cover types are likely to support greater densities and more diverse assemblages of nesting birds.

3.3 Wetlands

A total of 23 wetlands were identified in the OMF South study area, which are listed in Table G3.3-8 and are described further in Section 3.3.1, Wetland Descriptions. The wetland descriptions are organized consecutively, as wetlands were identified based on rights of entry and not geographically.

Of the 23 wetlands identified, 21 were fully or partially accessed during field reconnaissance and delineation surveys to assess wetland hydrology, soils, and vegetation. As of the time of this writing, the boundaries of 12 wetlands have been formally delineated and professionally surveyed in their entirety. The boundaries of nine wetlands (or portions of those wetlands) have been estimated using either a handheld global positioning system device or remote sensing and best professional judgment where access was limited. The one wetland that was not accessed for this study was delineated for the WSDOT SR 509 Project.

Wetland determination forms and rating forms for the wetlands accessed during the field surveys are provided in Attachments G3-4 and G3-5, respectively. Photographs of wetlands accessed during the field surveys and from public rights-of-way are included in Attachment G3-6. Wetland boundaries are shown in Figures G3.3-1 through G3.3-3.

Table G3.3-8 Wetlands in the Study Area

Wetland Name	Location[6]	HGM Classification[1]	USFWS Classification[2]	Approximate Wetland Area (Acres)	Wetland Rating (Ecology)[3]	Wetland Rating Habitat Points[4]	Jurisdiction	Wetland Buffer Width (Feet)[3,5]	Boundaries[7]

Notes:

(1) Hydrogeomorphic classification (Brinson 1993)

(2) PEM = palustrine emergent; PFO = palustrine forested; PSS = palustrine scrub-shrub, PAB = palustrine aquatic bed (Cowardin et al. 1979; FGDC 2013)

(3) Wetland ratings categorize wetlands based on their sensitivity to disturbance, their significance, their rarity, our ability to replace them, and the functions they provide (Hruby 2014). Category I wetlands have a very high level of function; Category IV wetlands have a low level of function. Ratings and regulatory buffer widths are preliminary and subject to change.

(4) Habitat points represent the score that is generated from the habitat analysis section of the wetland rating (Hruby 2014). Often habitat points are used to determine wetland buffer widths for local jurisdictions.

(5) Kent City Code 11.06.600.B; Federal Way Revised Code 19.145.420, Table 1

(6) Location of wetland relative to the site or mainline tracks (which includes the northern curve and tail tracks). Some wetlands are within both site and mainline areas.

(7) Surveyed = professionally surveyed; Estimated = boundaries based on existing information and aerial imagery or points collected with a handheld global positioning system unit; Surveyed/Estimated = wetland boundary contains both surveyed and estimated boundaries

.

3.3.1 Wetland Descriptions

3.3.1.1 Preferred and South 344th Street Alternatives

The Preferred and South 344th Street alternatives are both located in Federal Way. The site of the Preferred Alternative was largely undeveloped until 2004, when the Christian Faith Center was constructed. Portions of the South 344th Street Alternative site were developed as early as the 1960s, with substantial development occurring in the 1980s and 1990s. Both site alternatives are now occupied primarily by institutional and commercial development. The mainline tracks pass through Belmor and then continue south, adjacent to I-5. The mainline tracks for both the Preferred and South 344th Street Alternatives occupy the same footprint, except for the tail track options. Substantial residential development of the mainline track area appears to have started in the 1960s.

An undeveloped forested corridor, approximately 100 to 300 feet wide, exists adjacent to I-5 where East Fork Hylebos Tributary flows south along the eastern boundary of both sites partially on private property and partially within the WSDOT right-of-way. West Fork Hylebos Tributary flows through Wetland WFW-02 along the northwest corner of the Preferred Alternative.

The majority of the wetlands in the study area are associated with East Hylebos Tributary. One wetland, a Category II forested wetland identified as Wetland WFW-02, is contained within the in-line stormwater detention facility associated with West Fork Hylebos Tributary. The remaining wetlands are depressional or slope wetlands. Dominant vegetation communities are primarily forested or scrub-shrub.

Wetland WFW-01

Wetland WFW-01 is located west of I-5 and south of S 336th Street, along the eastern boundary of the Christian Faith Center property. The wetland is associated with East Fork Hylebos Tributary and includes both riverine and depressional elements.

This wetland primarily consists of deciduous forest communities dominated by Oregon ash, red alder, and black cottonwood. Salmonberry, red-twig dogwood, and vine maple are common understory plants. Slough sedge is common in wetter portions of the wetland, including areas that appear seasonally ponded. Reed canarygrass and Himalayan blackberry are present throughout the wetland. Primary hydrology for the wetland is overbank flooding from East Fork Hylebos Tributary, as well as high groundwater and stormwater runoff from nearby impervious surfaces. Soils in Wetland WFW-01 are silt or sandy loams that meet hydric soil indicators redox dark surface (F6) and thick dark surface (A12).

Wetland WFW-01 provides moderate water quality functions because it is a forested, well-vegetated, seasonally ponded wetland with an intermittently flowing outlet, and it also receives stormwater discharges. The wetland provides moderate water quality functions due to an intermittently flowing outlet and moderate ponding depths. The wetland provides moderate habitat functions, because it has diverse hydroperiods, multiple special habitat features, and is valuable due to proximity to East Fork Hylebos Tributary. Based on the above factors, Wetland WFW-01 received a Category III rating and a habitat score of 6. The regulated critical area buffer is 150 feet wide.

Wetland WFW-01 was described in the 2003 Christian Faith Center Environmental Impact Statement (where it was referred to as “Wetland B”) and includes approximately 5,400 square feet of created wetland and an additional 3,500 square feet of wetland enhancement as part of on-site mitigation from the site's previous development (City of Federal Way 2003).

Wetland WFW-02

Wetland WFW-02 is both a riverine and depressional wetland located east of SR 99 and south of S 336th Street in the northwest corner of the Christian Faith Center parcel. Wetland WFW-02 was in the study area for the Christian Faith Center Environmental Impact Statement (in which it was called "Wetland A"). No direct impacts on the wetland occurred during construction of the Christian Faith Center. Dominant vegetation in the wetland is forested and consists primarily of Pacific willow and black cottonwood. Dominant understory species include red-twig dogwood, salmonberry, and hardhack. Hydric soils in Wetland WFW-02 are a combination of histosols and silt loams that meet hydric soil indicators: histosol (A1), hydrogen sulfide (A4), and thick dark surface (A12). West Fork Hylebos Tributary flows through Wetland WFW-02, entering through a culvert under S 336th Street on the northern wetland boundary, and exiting through a standpipe on the west. The tributary lacks a defined channel as it flows through Wetland WFW-02.

This wetland was historically modified by Federal Way as part of a flood mitigation program, which resulted in construction of 4- to 6-foot-high earthen berms along the western and southern boundaries, which allow for greater stormwater storage. In addition to stormwater and stream flows, this wetland also likely receives hydrology from a locally high groundwater table. Wetland WFW-02 scored high for both water quality and hydrologic functions, primarily due to the ability to store large volumes of stormwater; however, the wetland has relatively low-quality forested habitat, and is surrounded on three sides by minimal buffers and substantial human development, resulting in a Category II wetland rating and a habitat score of 5. The regulated critical area buffer is 100 feet wide.

Wetland WFW-03

Wetland WFW-03 is a riverine wetland located along both sides of East Fork Hylebos Tributary in the WSDOT right-of-way west of I-5. Hydrology for Wetland WFW-03 appears to be derived primarily from overbank flooding, as well as groundwater discharge. Wetland WFW-03 receives stormwater discharge from nearby commercial development, as well as surface runoff from I-5.

This wetland primarily consists of a palustrine deciduous forested community. Dominant species include Oregon ash, black cottonwood, and Pacific willow. Dominant understory species include salmonberry, with small pockets of slough sedge. Soils in Wetland WFW-03 meet hydric soil indicator redox dark surface (F6).

Wetland WFW-03 scored high for water quality functions due to the presence of trees and shrubs that filter pollutants and because the wetland is located within a UGA and in close proximity to I-5, which generates excess pollutants. Wetland WFW-03 scored moderate for hydrologic functions since it contains trees and shrubs that slow down water velocities during floods and is located upstream from areas with flooding problems. The wetland scored moderate for habitat functions because it has diverse hydroperiods, multiple special habitat features, and is in proximity to multiple priority habitats. Based on the above factors, Wetland WFW-03 received a Category III rating and a habitat score of 6. The regulated critical area buffer is 150 feet wide.

Wetland WFW-04

Wetland WFW-04 is a depressional wetland located at the edge of the WSDOT right-of-way near a stormwater facility west of I-5, between S 341st Place and S 344th Street. Vegetation in the wetland is dominated by Oregon ash, Pacific willow, and black cottonwood, with an understory consisting primarily of hardhack. Hydric soils in Wetland WFW-04 are a silt loam with high organic content that meet hydric soil indicators, redox dark surface (F6). Hydrology inputs to Wetland WFW-04 include overflow from the adjacent stormwater facility, as well as stormwater inputs from surrounding commercial properties and a high groundwater table. Wetland WFW-04 is a closed depression with no outlet, making it score high for water quality functions. Wetland WFW-04 scored moderate for hydrologic functions because it provides some storage during wet periods and is in proximity to I-5, which generates excess runoff. However, the wetland has relatively poor quality habitat and degraded buffers; it therefore scored low for habitat functions resulting in a Category III rating and a habitat score of 4. The regulated critical area buffer is 80 feet wide.

Wetland WFW-05

Wetland WFW-05 is a riverine wetland located along East Fork Hylebos Tributary between S 344th Street and the offramp from southbound I-5 to Highway 18. This wetland supports both coniferous and deciduous forested communities and is dominated by western redcedar, Oregon ash, and black cottonwood, with an understory of hardhack, Sitka willow, and twinberry. Soils within the wetland are silt loam and meet hydric soil indicator thick dark surface (A12). Primary hydrology inputs for the wetland appear to be from overbank flooding of East Fork Hylebos Tributary, although depressions within the wetland appear to hold water outside of flood events. Wetland WFW-05 has high potential for water quality functions due to dense tree and shrub layers within the wetland, as well as a location within an incorporated city; it has moderate hydrologic potential due to a moderate ability to reduce flood velocities, and it has moderate habitat potential due to its lack of habitat complexity and lack of accessible connections to other habitats on a broader landscape scale despite the presence of priority habitats nearby. Overall, Wetland WFW-05 received a Category III rating and a habitat score of 6. The regulated critical area buffer is 150 feet wide.

Wetland WFW-06

Wetland WFW-06 is a small slope wetland located in the WSDOT right-of-way west of I-5, between S 336th Street and S 344th Street. This wetland is located in an apparently excavated swale feature that drains stormwater from I-5 to East Fork Hylebos Tributary. Although the majority of the swale does not meet the definition of wetland, the far southern end has sufficient hydrology to produce hydric soils meeting indicator redox dark surface (F6) and to support hydrophytic vegetation. The wetland is dominated by scrub-shrub vegetation, primarily salmonberry. Wetland WFW-06 is found on a relatively gentle slope with dense herbaceous vegetation in a basin where water quality is an issue; it therefore scored moderate for water quality functions. Given the stormwater inputs to the wetland, Wetland WFW-06 scored moderate for hydrologic functions. Wetland WFW-06 scored moderate for habitat functions due to proximity to priority habitats. Overall, Wetland WFW-06 received a Category IV rating and a habitat score of 5. The regulated critical area buffer is 50 feet wide.

Wetland WFW-07

Wetland WFW-07 is a small riverine wetland located in the northeast section of Belmor adjacent to golf course greens. Within the Belmor golf course, East Fork Hylebos Tributary has been channelized, and a build-up of sediment has resulted in several wetland benches that are below the OHWL.

The palustrine scrub-shrub and emergent wetland is dominated by Himalayan blackberry, hardhack, Sitka willow, reed canarygrass, and giant horsetail. Hydric soils met two indicators: depleted matrix (F3) and depleted below dark surface (A11).

Wetland WFW-07 scored moderate for water quality because it contains some trees, shrubs, and herbaceous plants that improve water quality by filtering pollutants, and because it is located within an urban growth area (UGA) and within a golf course that produces pollutants for the wetland to filter. The hydrologic function score was low due to only some plants slowing water velocities and the potential to reduce flooding is provided by its location in a UGA, which contributes to higher stream flows. The wetland scored low on habitat due to its lack of habitat complexity and lack of connections to other habitats. Overall, Wetland WFW-07 received a Category III rating and a habitat score of 4. The regulated critical area buffer is 80 feet wide.

Wetland WFW-08

Wetland WFW-08 is a small, riverine wetland located in the northeast section of Belmor adjacent to golf course greens. Wetland WFW-08 is south (downstream) of Wetland WFW-07, separated by a 48-inch concrete culvert. Wetland WFW-08 consists of several bench wetlands located below the OHWL, in which the primary source of hydrology is provided by East Fork Hylebos Tributary. The stream has been channelized in this section.

The palustrine scrub-shrub and emergent wetland is dominated by Himalayan blackberry, Sitka willow, cattail, reed canarygrass, and slough sedge. Soils were dark and underlain by a restrictive layer composed of quarry spalls. Hydric soils in the scrub-shrub and emergent vegetation classes were dark, but indicators were problematic, likely due to widespread land surface modifications and site development. However, the presence of strongly hydrophytic plants, the primary indicators of wetland hydrology, and the wetland’s landscape position within the active floodplain support the assumption that the soils were hydric and therefore the presence of wetland conditions.

Wetland WFW-08 scored low for water quality functions because the wetland’s ability to retain water and to filter pollutants is limited. The wetland scored moderate for hydrologic functions due to its moderate ability to retain water, attenuate water velocities, as well as having a moderate water input from the immediate surrounding area and contributing basin. The wetland scored low on habitat due to its lack of habitat complexity and lack of connections to other habitats. Overall, Wetland WFW-08 received a Category III rating and a habitat score of 4. The regulated critical area buffer is 80 feet wide.

Wetland WFW-09

Wetland WFW-09 is a small riverine wetland located in the southeastern section of Belmor. Wetland WFW-09 is south (downstream) of Wetland WFW-08, separated by twin 18-inch culverts. Wetland WFW-09 consists of several bench wetlands located below the OHWL, in which the primary source of hydrology is provided by East Fork Hylebos Tributary, which has been channelized in this section.

The palustrine scrub-shrub wetland is dominated by Himalayan blackberry, hardhack, and Sitka willow. Hydric soils were dark and/or had a depleted matrix in lower layers and met the hydric soil indicators depleted matrix (F3) and depleted below dark surface (A11) within the scrub-shrub vegetation class.

Wetland WFW-09 scored moderate for water quality because trees and shrubs filter out pollutants, and because it is located within a UGA and within a golf course that produces pollutants for the wetland to filter. The hydrologic function scored moderate because trees and shrub slow water velocities and because the potential to reduce flooding is provided by its location in a UGA, which contributes to higher stream flows. The wetland scored low on habitat due to its lack of habitat complexity and lack of connections to other habitats. Overall, Wetland WFW-09 received a Category III rating and a habitat score of 4. The regulated critical area buffer is 80 feet wide.

Wetland WFW-10

Wetland WFW-10 is a riverine wetland with three wetland units (a, b, and c) located between S 330th Street and S 333rd Street on multiple parcels. Wetland WFW-10 is south (downstream) of Wetlands WFW-12 and WFW-09 and is separated from other wetlands by twin 18-inch culverts. The primary source of hydrology was provided by East Fork Hylebos Tributary and a high groundwater table.

The palustrine forested wetland is dominated by western redcedar, black cottonwood, red alder, Oregon ash with Himalayan blackberry, salmonberry, lady fern, slough sedge, and Kentucky bluegrass in the understory. Hydric soils were dark and/or had a depleted matrix in lower layers. Within Unit A, hydric soils met the hydric soil indicators hydrogen sulfide (A4) and thick dark surface (A12). Hydric soils in Unit B met the hydric soil indicator redox dark surface (F6). Within Unit C, hydric soils met the indicator depleted below dark surface (A11).

The three units are rated together because of their similarity and association with East Fork Hylebos Tributary. These riverine wetlands lack hydrologic constrictions or vegetation breaking larger than 50 feet that would divide them into separate rating units. Wetland WFW-10 scored moderate for water quality functions because its high density of trees and shrubs filter out pollutants, and it is located within a UGA and a dense residential area that contribute pollutants. It scored moderate for hydrologic functions as tree and shrub cover slow down water velocities, and because its potential to reduce flooding is provided by its location in a UGA, which contributes to higher stream flows. The wetland received a low score for habitat functions because it generally lacks habitat complexity and connectivity to other habitats. Overall, Wetland WFW-10 received a Category III rating and a habitat score of 5. The regulated critical area buffer is 80 feet wide.

Wetland WFW-11

Wetland WFW-11 is a depressional wetland located between 24th Avenue S and I-5 in Federal Way both on private land and in the WSDOT I-5 right-of-way. Wetland hydrology was supported by a high groundwater table and precipitation.

The wetland is dominated by black cottonwood, red alder, Oregon ash, Sitka willow, hardhack, and Himalayan blackberry in the forested class, and reed canarygrass in the emergent vegetation class. Hydric soils were depleted below a dark upper layer and met the indicators depleted matrix (F3) and depleted below dark surface (A11) within the forested vegetation class and the indicators redox dark surface (F6) in the emergent vegetation class.

Wetland WFW-11 scored moderate for water quality functions because its outlet flows intermittently providing moderate retention time for filtration. Persistent plants that filter pollutants cover most of the wetland, and surrounding land within the immediate vicinity and within the watershed provide some pollution input that may be filtered by the wetland. Hydrologic functions to reduce flooding within the watershed also scored as moderate due to some water storage capacity, moderate surface water inputs, and flooding problems lower in the watershed. The wetland scored low for habitat functions due to moderate habitat complexity within the wetland and lack of connections to other habitats. Overall, Wetland WFW-11 received a Category III rating and a habitat score of 5. The regulated critical area buffer is 80 feet wide.

Wetland WFW-12

Wetland WFW-12 is a small riverine wetland located at the south end of Belmor and extending into two adjacent parcels. The primary sources of hydrology are flooding from East Fork Hylebos Tributary and a high groundwater table. Wetland WFW-12 is south (downstream) of Wetland WFW-09, separated by a 41-inch pre-cast concrete culvert. Wetland WFW-12 consists of several bench wetlands located below the OHWL.

The palustrine emergent, scrub-shrub, and forested wetland is dominated by red alder, salmonberry, Himalayan blackberry, reed canarygrass, and creeping buttercup. Hydric soil observed in this wetland were largely depleted, but indicators were problematic, likely due to widespread land surface modifications and site development. However, the presence of hydrophytic plants and several primary indicators of wetland hydrology, combined with its landscape position within the active floodplain, support the assumption that hydric soils are present. The wetland boundary was determined by the extent of fill material and evidence of frequent inundation.

Wetland WFW-12 scored moderate for water quality because trees and shrub plants filter out pollutants, and because it is located within a UGA and within a residential area that produces pollutants for the wetland to filter. The hydrologic function score was moderate because trees and shrubs slow water velocities within the wetland, and because it has potential to reduce flooding through its location in a UGA that also has flooding problems downstream. The wetland scored low on habitat due to its combination of moderate habitat complexity and lack of connections to other habitats. Overall, Wetland WFW-12 received a Category III rating and a habitat score of 5. The regulated critical area buffer is 80 feet wide.

Wetland WFW-13

Wetland WFW-13 is a small slope wetland located within a ditch in the WSDOT right-of-way east of I-5 and south of S 333rd Street. The ditch continues south where eventually it transitions to a riprap-lined ditch, and then ends. Wetland WFW-13’s primary sources of hydrology are a high groundwater table and precipitation.

The palustrine scrub-shrub wetland has sparse vegetation, which is dominated by Himalayan blackberry and reed canarygrass. Hydric soils consisted of a depleted matrix overlain by dark soils, which had a restrictive layer of clay and gravel starting at 17 inches below ground level. Hydric soils met the indicators depleted matrix (F3) and depleted below dark surface (A11).

Wetland WFW-13 scored low for water quality because it lacks dense vegetation that can filter pollutants that it receives from highway runoff, and it does not contribute much value to reducing pollutants within the broader watershed. Its hydrologic function score was also low because it lacks the vegetation to slow water velocities. The wetland scored low for habitat functions because it does not have any habitat complexity and lacks connections to other habitats.

Overall, Wetland WFW-13 received a Category IV rating and a habitat score of 3. The regulated critical area buffer is 50 feet wide.

Wetland WFW-14

Wetland WFW-14 is a depressional wetland located in a stormwater pond with wetland characteristics just north of S 336th Street. Its primary source of hydrology is precipitation and stormwater from the nearby apartment complex. Water from the stormwater pond flows south through a culvert and empties into East Fork Hylebos Tributary at S 336th Street.

This palustrine emergent wetland is dominated by Kentucky bluegrass and creeping buttercup. Hydric soils included a depleted matrix (F3).

Wetland WFW-14 scored low for water quality functions due to the lack of persistent, ungrazed plants and low retention time for water in the wetland to filter pollutants. The wetland scored low for hydrologic functions due to the lack of ability to hold back water, even though water inputs are high in the developed contributing basin. Habitat functions are also low due to the lack of structural and habitat diversity and lack of connections to other habitats. Overall, Wetland WFW-14 received a Category IV rating and a habitat score of 4. The regulated critical area buffer is 50 feet wide.

According to King County assessor data and historic aerial imagery, the stormwater pond appears to have been created between 1998 and 1999 during construction of the associated apartment complex. It is unknown whether the stormwater pond was excavated from wetland or upland. Wetlands are not mapped at this site by NWI, Federal Way, or King County iMap, nor do historic aerial photos indicate the presence of a wetland. However, the stormwater pond’s proximity to East Fork Hylebos Tributary, historic topographic maps, and the abundance of nearby wetlands associated with the stream suggest the possibility that a wetland could have been present in this area historically.

Wetland WFW-15

Wetland WFW-15 is a riverine wetland associated with East Fork Hylebos Tributary located north of S 336th Street. The palustrine scrub-shrub and forested wetland is dominated by salmonberry and red alder. Its primary source of hydrology includes overbank flooding from stream and a high groundwater table. Hydric soils in Wetland WFW-15 are dark or depleted silt, clay, or gravelly sandy loams. They meet hydric soil indicator depleted below dark surface (A11) and redox dark surface (F6).

Wetland WFW-15 scored moderate for water quality because trees and shrub plants filter out pollutants, and because it is located within a UGA and within a residential area that produces pollutants for the wetland to filter. The hydrologic function score was moderate because trees and shrubs slow water velocities within the wetland, and because it has potential to reduce flooding through its location in a UGA that also has flooding problems downstream. The wetland scored low on habitat due to its combination of moderate habitat complexity and lack of connections to other habitats.

The rating for Wetland WFW-15 is Category III, with a habitat score of 6. The regulated critical area buffer is 150 feet wide.

Wetland WFW-16

Wetland WFW-16 is a depressional wetland located at the north end of the Federal Way/S 320th Street park-and-ride. Its primary source of hydrology includes stormwater inputs, a high groundwater table, and precipitation. The palustrine emergent and scrub-shrub wetland is dominated by Himalayan blackberry, hardhack, reed canarygrass, cattail, and slough sedge. Hydric soils were depleted and met the indicators for depleted matrix (F3) and depleted below dark surface (A11).

Wetland WFW-16 scored moderate for water quality functions due to the presence of persistent, ungrazed plants and retention time for water in the wetland to filter pollutants. The wetland scored moderate for hydrologic functions due to the ability to retain water and large inputs from the developed contributing basin. Habitat functions are low due to the lack of structural and habitat diversity and lack of connections to other habitats. Overall, Wetland WFW-16 received a Category III rating and a habitat score of 3. The regulated critical area buffer is 80 feet wide.

Wetland WFW-17

Wetland WFW-17 is a riverine wetland located west of I-5 and south of S 344th Street. The wetland is adjacent to East Fork Hylebos Tributary. Vegetation in the wetland is dominated by black cottonwood, with an understory of twinberry and salmonberry. Hydric soils in Wetland WFW-17 are silt loams that meet hydric soil indicator depleted below dark surface (A11). Wetland hydrology is supported by overbank flooding from East Fork Hylebos Tributary and a high groundwater table. Wetland WFW-17 has an intermittently flowing outlet and dense persistent vegetation, resulting in a moderate score for water quality functions. Due to intensive surrounding land uses and flooding problems downstream of the wetland, Wetland WFW-17 received a moderate score for hydrologic functions. Wetland WFW-17 scored moderate for habitat functions due to its proximity to priority habitat features. Overall, Wetland WFW-17 received a Category III rating and a habitat score of 5. The regulated critical area buffer is 80 feet wide.

Wetland WFW-18

Wetland WFW-18 is a riverine wetland located west of I-5 and south of S 344th Street and is located north of Wetland WFW-17 on the same property. Wetland WFW-18 is adjacent to East Fork Hylebos Tributary. The wetland is dominated by scrub-shrub vegetation, including primarily Scouler’s willow, with reed canarygrass present in emergent areas. Soils within the wetland are silt loam and meet hydric soil indicator redox dark surface (F6). Wetland hydrology is supported by a local high groundwater table. Wetland WFW-18 contains areas that occasionally flood as well as an intermittently flowing outlet to East Fork Hylebos Tributary. The intermittently flowing outlet and dense persistent vegetation results in a moderate score for water quality functions. Due to the presence of widespread persistent, ungrazed plants, the wetland received a moderate score for hydrologic functions. Wetland WFW-18 scored moderate for habitat functions due to its proximity to priority habitat features, resulting in a Category III rating and a habitat score of 5. The regulated critical area buffer is 80 feet wide.

Wetland WFW-21

Wetland WFW-21 is a small, riverine wetland located off I-5 in a highway cloverleaf. Wetland WFW-21 is associated with East Fork Hylebos Tributary. A culvert is the outlet from Wetland WFW-21 to East Fork Hylebos Tributary downstream. The primary sources of hydrology for the wetland are flooding and a high groundwater table from the stream. Wetland WFW-21 contains a palustrine scrub-shrub vegetation community, consisting of Pacific nine-bark, Himalayan blackberry, Scouler’s willow, red alder, and salmonberry. Soils found throughout Wetland

WFW-21 meet hydric soil indicator redox dark surface (F6). The wetland boundary was determined by the extent of fill material and evidence of frequent inundation.

Wetland WFW-21 scored moderate for water quality functions because shrubs filter out pollutants, and because it is located within a UGA and in an area that produces pollutants for the wetland to filter. The hydrologic function score was moderate because vegetation slows water velocities within the wetland, and the wetland is in a UGA that contributes to higher stream flows. The wetland scored moderate for habitat functions because it has some habitat complexity and multiple special habitat features, and it is near multiple priority habitats.

Wetland WFW-21 is rated Category III, with a habitat score of 6. The regulated critical area buffer is 150 feet wide.

Wetland WFW-22

Wetland WFW-22 is a small, depressional wetland located on the far western side of an I-5 cloverleaf, north of Wetland WFW-21. Wetland WFW-22 is not associated with East Fork Hylebos Tributary. The wetland is a localized depression that receives its primary source of hydrology from stormwater and precipitation. Wetland WFW-22 contains a palustrine scrub-shrub community, consisting of red osier dogwood, black cottonwood, and Himalayan blackberry. Soils sampled in Wetland WFW-22 meet the criteria for the hydric soil indicator depleted matrix (F3). The wetland boundary was determined by a change in topography and evidence of frequent inundation.

Wetland WFW-22 scored moderate for water quality functions because it receives runoff from areas that generate pollutants, and it is in a basin where water quality is an issue. Based on intensive land uses in surrounding areas, combined with flooding problems in the same subbasin, Wetland WFW-22 received a moderate score for hydrologic functions. The wetland scored low on habitat due to its lack of habitat complexity and lack of connections to other habitats.

Wetland WFW-22 is rated Category III, with a habitat score of 4. The regulated critical area buffer is 80 feet wide.

Wetland WFW-32

Wetland WFW-32 is classified as a depressional wetland with palustrine scrub-shrub and emergent wetland plant communities. It is located at the west side of the Federal Way/S 320th Street Park and Ride and east of 23rd Avenue S. The wetland is a linear depression that receives water from a high groundwater table and from the parking lot and intermittently outflows into a stormwater pond to the north. From the stormwater pond, water flows through pipes to the East Fork Hylebos Creek Tributary 0016A and daylights in Belmor. Soils sampled meet hydric soil indicator depleted matrix (F3) and depleted below dark surface (A11). Dominant vegetation includes Himalayan blackberry, hardhack, reed canarygrass, creeping buttercup, and soft rush.

Wetland WFW-32 provides a moderate value in both water quality and hydrologic functions, primarily due to its ability to store some stormwater and the presence of plants to filter and attenuate flows. The wetland has a low habitat function because it lacks plant diversity and lack habitat features.

Wetland WFW-32 is rated IV rating and a habitat score of 3. The regulated critical area buffer is 50 feet.

Wetland WFW-33

Wetland WFW-33 is classified as a depressional/riverine wetland associated with a palustrine forested wetland plant community. Wetland WFW-33 is located between S 333rd Street and S 366th Street. It is located north of Wetland WFW-02. The wetland boundary was mapped using topography, aerial imagery, and observations from the roads. The wetland is associated with the West Fork Hylebos Tributary 0014C, which contributes water to the wetland. Wetland WFW-33 likely contains areas that occasionally and seasonally flood. Observations from the road and aerial imagery show red alder and black cottonwood in the canopy with Himalayan blackberry, salmonberry and reed canarygrass in the understory.

Wetland WFW-33 provides moderate to high value in both water quality and hydrologic functions, primarily due to its ability to store stormwater and the presence of dense vegetation. The wetland provides an overall low value in habitat function, due to minimal habitat interspersion and proximity to a substantial amount of development and human-made structures.

Wetland WFW-33 is rated II rating and a habitat score of 5. The regulated critical area buffer is 150 feet.

3.3.1.2 Midway Landfill Alternative

The Midway Landfill Alternative is in Kent, primarily on the Midway Landfill site owned by Seattle Public Utilities. The site has been subject to extensive past human disturbances. The site was originally a hillslope, which was then mined as a gravel pit from 1945 to 1968. Following use as a gravel pit, the site was used as a landfill from 1966 to 1983. After methane gas was discovered in the surrounding residential area in 1984, the site was placed on the U.S. Environmental Protection Agency (EPA) Superfund National Priorities List (Opalski 2010). In response, the site was capped with a multi-layered landfill cover system, including a low-permeability silt/silty clay, a 50-millimeter synthetic membrane, a geonet drainage layer, 1 foot of sand, and 1 foot of topsoil planted with shallow-rooted grasses (EPA 2000). A surface water management system was completed, which consisted of site filling and grading to control surface water drainage and prevent surface water from infiltrating into the landfill. These systems were designed to greatly reduce the amount of rain that would seep into the landfill. The landfill site continues to be actively managed and monitored since initial cleanup efforts were completed in 1991. The sand layer is regularly regraded to eliminate standing water. Vegetation on the landfill is regularly mowed throughout the growing season and consists entirely of grasses and herbaceous vegetation.

This site was investigated for wetlands, and five areas that met the three parameters for wetlands were identified. During preparation of the 2021 SEPA Draft EIS, the U.S. Army Corps of Engineers (Corps) determined that the areas do not meet federal criteria for jurisdictional wetlands (Tong 2019), and Ecology verified that they are non-jurisdictional under state definitions (Gresham 2020). On May 25, 2023, the Supreme Court issued a judgment limiting Corps jurisdiction on "waters of the U.S." The Corps is expected to issue a new rule that will revise the definitions of waters of the U.S. in fall 2023. Ecology, which has state authority under RCW 90.48 to regulate wetlands, will likely issue administrative orders to address impacts to waters of the U.S. the Corps no longer regulates. In the case of these five areas at the Midway Landfill, Sound Transit believes that it is not likely the earlier determination will change because the Supreme Court judgment limits jurisdiction. As such, these areas are not considered regulated wetlands and are not discussed further. However, if the definition of waters of the U.S. were to expand and the Midway Landfill is selected as the project to be built, Sound Transit will comply with the applicable regulations and update project documentation as required. One additional wetland at the Midway Landfill Alternative – Wetland 148.67L – is located in the WSDOT right-of-way of I-5. This wetland was not accessed during field reconnaissance surveys but was delineated as part of the WSDOT SR 509 Project.

Wetland WL148.67L

Wetland WL148.67L is a small, depressional wetland located in the WSDOT right-of-way of southbound I-5. It was delineated in April 2019 by Anchor QEA as a component of the SR 509 Completion Stage 1B Project (Anchor 2019). Dominant vegetation in forested areas includes black cottonwood; shrub areas are dominated by salmonberry, hardhack, and willow. Slough sedge and violet are present in emergent areas. Hydrology in the wetland is from surface runoff, including stormwater runoff from I-5. Soils in the wetland are primarily silt loam and meet hydric soil indicator F6, redox dark surface. Wetland WL148.67L is a closed depression and scored high for water quality and moderate for water quality functions. Given the proximity to I-5 and lack of connections to other habitats, Wetland WL148.67L scored low for habitat functions. Overall, Wetland WL148.67L received a Category III rating and a habitat score of 4. The regulated critical area buffer is 75 feet wide.

4 ENVIRONMENTAL IMPACTS

This section describes the potential impacts of the OMF South project alternatives on aquatic resources, terrestrial resources, and wetlands. See Section 2.4, Impact Assessment Methods and Assumptions, for a discussion of how impacts were identified and evaluated. Analyses of project-related impacts assume that the BMPs described in Section 5, Mitigation Measures, would be implemented and would perform as expected to avoid and minimize certain impacts during construction. For each resource area, analyses of direct impacts are divided between long-term (operational) impacts and short-term (construction-related) impacts. Indirect effects are evaluated in Section 4.4; cumulative impacts are evaluated in Section 4.5.

4.1 Aquatic Species and Habitat

Analyses in this subsection address the potential long-term and temporary (i.e., construction-related) impacts of each alternative on streams, aquatic species and habitat. Actual impacts would depend on the location and design of the final alternative, the construction footprint and methods, the BMPs implemented during construction (see Section 5.1.1, Avoidance and Minimization During Design Development and Section 5.1.2, Construction Best Management Practices), and the performance of post-construction restoration.

Sound Transit considered the following potential impacts on aquatic resources:

- Permanent loss of physical habitat (fill)
- Permanent degradation of in-stream physical habitat, such as shading, removal of boulders or LWD from the channel, and loss of riparian vegetation function (loss of nutrient inputs, LWD recruitment, and shade)
- Impacts on fish passage
- Altered hydrology (higher peak flows result in increased scour/deposition downstream, decreased percolation from impervious surfaces results in lower base flows)
- Increased nighttime lighting
- Temporary or permanent degradation of water quality (increased temperature, increased turbidity, increased loading of heavy metals and hydrocarbons)
- Temporary loss of physical in-stream habitat (dewatering, temporary piping during stream relocation or culvert replacement)
- Temporary degradation of habitat (sedimentation, removal of riparian vegetation, disturbance to stream banks)

To the extent that impacts cannot be avoided or minimized through project design changes and use of BMPs, Sound Transit would implement additional measures to reduce adverse effects and provide compensatory mitigation measures where adverse effects are unavoidable. Sound Transit has committed to achieving no net loss of ecosystem function on a project-wide basis (Sound Transit 2007). As discussed in Section 5.3, Compensatory Mitigation, compensatory mitigation would be implemented in accordance with applicable federal, Tribal, state, and local requirements and guidelines.

As discussed in Section 3.1.2, Aquatic Species of Concern, no aquatic species of concern are known or expected to use habitats in the study area under current conditions. Based on intermittent flows, the lack of pools deep enough to remain wetted during dry periods, and the presence of human-created barriers to fish passage, salmonids are neither known nor expected to use either of the Hylebos Creek tributaries. However, the basin sizes, channel widths, and stream gradients of both tributaries indicate the potential to support fish in the future. There are no surface-flowing segments of North Fork McSorley Creek in the study area, and the reach of North Fork McSorley Creek that receives stormwater runoff from the study area is not accessible to anadromous salmonids.

In anticipation of the need for federal approval for construction and operation of OMF South facilities in the I-5 right-of-way, Sound Transit has started preparing a biological assessment to support ESA Section 7 consultation with NMFS and USFWS. The assessment would also include a review of potential effects on Essential Fish Habitat, as required by the Magnuson-Stevens Fishery Conservation and Management Act.

4.1.1 No-Build Alternative

Under the No-Build Alternative, impacts to aquatic resources from construction or operation of OMF South would not occur. However, for the purposes of this technical report, the No-Build Alternative assumes that by the design year 2042, all planned Sound Transit 3 projects, including FWLE and TDLE, are built along with the other public and private projects planned within the study area. TDLE overlaps with the OMF South Preferred and South 344th Street alternatives. If TDLE is constructed as proposed, the mainline track associated with these OMF alternatives would be built later in time. Impacts associated with construction of the mainline track are addressed within the build alternatives impacts discussion below. All other TDLE-related impacts are addressed in Section 4.5, Cumulative Impacts.

4.1.2 Long-Term Impacts

Direct long-term impacts on aquatic resources would occur where permanent features such as project facilities (including lead, mainline, and test tracks) permanently alter in-stream habitat (including habitat accessibility) or riparian functions. Additional impacts may occur where surface waters receive stormwater runoff from impervious surfaces created or replaced by project construction. Aquatic species may also be affected by increases in the amount of light reaching surface waters at night. These potential effects are described in greater detail below. Impacts associated with each alternative are discussed in the subsections that follow.

In-Stream Habitat Alteration

None of the stream segments in the study area are known or expected to support use by salmonids under current conditions. Other aquatic organisms, such as invertebrates and non-salmonid fish, are likely present in study area streams. The construction of mainline or lead tracks could permanently alter in-stream habitat in areas where the elevated mainline or lead tracks run close to or cross the stream. In addition, the loss or degradation of stream habitat could reduce the availability of prey (e.g., benthic invertebrates) for fish and other aquatic species in reaches downstream of the study area. Impacts on stream habitat could also decrease the availability and quality of stream habitats in the future if access is eventually restored through the removal of downstream fish passage barriers. Any work below the OHWL of any streams in the study area would be conducted in accordance with the terms of the Hydraulic Project Approval (HPA), Clean Water Act Section 404 permit and other applicable permits obtained for this project.

Sound Transit has committed to minimizing the need to place existing streams in new culverts and has designed the OMF South alternatives to avoid new stream piping whenever possible. However, two to three culverts may need to be replaced as part of the Preferred Alternative, and these replaced culverts, which may be longer, would be made fish passable. If any culverts on potentially fish-bearing streams are replaced, the replacement structures would be designed and installed in accordance with WDFW’s Water Crossing Design Guidelines (Barnard et al. 2013). Unavoidable impacts on streams are described in the discussions of the impacts of the alternatives, below.

Impacts may also occur where elevated segments of mainline, lead, or test tracks pass over surface-flowing streams. In addition to affecting riparian habitat vegetation (see the discussion of Vegetation Removal and Habitat Alteration, below), shade from structures placed over streams may affect the behavior of fish that could enter the affected stream segments if access is restored in the future. Outmigrating juvenile salmonids may respond to shadows by pausing at the upstream end of the darkened area, potentially increasing their vulnerability to predation (Kemp and Williams 2008). These impact areas and the length of the streams affected are summarized in Table G3.4-1.

In some areas, restored, daylighted channels would be constructed for stream segments currently contained within culverts. Daylighting would allow increased interaction between the stream and associated riparian vegetation, resulting in beneficial effects associated with restoring natural processes such as organic input and flow attenuation.

Evaluations of the potential impacts of the alternatives on in-stream habitat conditions are based on the length of surface-flowing streams within the project limits, as well as on the length of stream channel that would be relocated or daylighted (Table G3.4-1). Impacts are depicted in Figures G3.4-1 through G3.4-6.

The impacts described in Table G3.4-1 reflect potential long-term impacts to streams and aquatic resources, based on the overlap between streams or stream buffers and the permanent impact footprint for each alternative. Impacts to aquatic resources within the permanent impact footprint could take several forms. For example, in some areas, project features (including elevated structures such as the mainline, lead, and test tracks) would be built near or over surface-flowing stream channels. In such areas, no ground-disturbing work would take place in the stream channel, but the presence of those structures could have long-term effects on riparian and/or aquatic habitats. In other areas, an existing stream channel would need to be relocated and realigned to accommodate project features. These impacts are described further in the discussions of the impacts of the individual alternatives.

As discussed in Section 2.4.4, Analysis Assumptions, the impact values and areas in the table and figures represent conservative estimates of the impacts of the alternatives. Not all areas within the permanent impact footprint would be converted to structures or hard surfaces. Actual anticipated impacts would be determined when an alternative is selected to be built and (unless the No-Build Alternative is selected) the project design is sufficiently advanced to undergo permitting review.

Table G3.4-1 Potential Long-Term Impacts on Aquatic Resources

Midway Landfill	N/A	N/A	N/A	0	0	0	0	0

Notes:

(1) Both affected streams are Type F, per WAC 222-16-030.

(2) Includes the total length of surface-flowing stream within the permanent impact footprint defined for this analysis.

(3) Impact numbers presented in this table represent all affected areas inside functional stream buffers, including areas that overlap with wetland buffers.

(4) The portion of this stream in the study area lacks a defined bed and bank where it flows through Wetland WFW-02. For this reason, stream impacts are based on the approximate centerline of the mapped stream. Permanent impacts on the stream buffer are calculated as the affected area of Wetland WFW-02. See text for further discussion.

(5) If neither the Preferred nor South 344th Street alternative is selected, the mainline could be built later in time if TDLE is constructed as proposed. TDLE is currently under environmental review.

Fish Passage

No impacts on anadromous fish passage are anticipated because none of the stream reaches in the study area are currently accessible to anadromous fish. This analysis considers impacts that could affect the potential availability and accessibility of stream habitats in the future if access is restored through the removal of downstream fish passage barriers.

As discussed above, Sound Transit has committed to minimizing the need to place existing streams in new culverts and has designed the OMF South alternatives to avoid new stream piping whenever possible. However, existing culverts at S 336th Street and S 344th Street may need to be replaced for the Preferred Alternative or the South 344th Street Alternative, as discussed in the analyses of the impacts of those alternatives, below. These replaced culverts, which may be longer, would be made fish passable.

If any culverts must be installed or replaced for this project, they would be designed and installed in accordance with WDFW's Water Crossing Design Guidelines (Barnard et al. 2013). Decisions about culvert design would be based on the assumption that all surface-flowing stream segments in the study area have the potential to support fish use in the future. As such, culverts replaced for project construction would not impede fish access through the study area in the future, if access is restored through the removal of downstream fish passage barriers. In addition, Sound Transit would coordinate with WSDOT to ensure that the development of the OMF provides adequate space for any future replacement of WSDOT-owned culverts that are currently barriers to fish passage.

Vegetation Removal and Habitat Alteration

Where the permanent impact footprint overlaps a riparian buffer, the ecological function of that buffer would be diminished. Substantial decreases in current riparian function would occur where areas of tree or shrub cover in a stream's riparian zone are converted to facilities or to vegetation types (e.g., lawns, ornamental landscaping) with less structural or compositional diversity. Where riparian vegetation, regardless of current condition, is removed altogether, potential future riparian functions would be eliminated. Potentially affected riparian functions and processes include fish and wildlife habitat; food chain support; water temperature maintenance; infiltration; groundwater recharge and discharge; sediment delivery, transport, and storage; organic matter input; nutrient and pathogen removal; and stream channel formation and maintenance.

Based on the urban setting of the study area and disturbed riparian corridors, comparisons of the impacts of the alternatives on riparian habitat are based on the overlap between the project limits[3] and functional stream buffers. As discussed previously, functional stream buffers are defined as standard regulatory buffers for streams that have been trimmed at the edge of existing developed areas. For the two streams addressed in this analysis, this amounts to the contiguous vegetated areas within 100 feet of surface-flowing stream segments that are interrupted by roads, buildings, and institutional or industrial complexes. This reduces the capacity of riparian functions and processes in the OMF South study area. It is widely recognized that the loss of forest habitat can adversely affect riparian functions – the recruitment of wood in particular (Knutson and Naef 1997). Moreover, studies conducted in western Washington, western Oregon, and southeastern Alaska indicate that more than 90 percent of LWD input to streams from riparian areas is recruited from the areas within approximately 100 feet of the stream's edge (Murphy and Koski 1989; McDade et al. 1990; McKinley 1997; Martin et al. 1998).

---

[3] This would include areas within the zone that would be cleared and maintained on either side of the connecting tracks.

Other functions, such as water quality protection, channel maintenance, and detrital input, occur primarily in the first 100 feet (Fischer and Fischenich 2000).

Permanent project-related impacts on riparian habitat would also occur where segments of mainline, test, or lead tracks span areas of riparian vegetation. For operational safety, trees and other tall vegetation would not be allowed to grow near track segments. Where the track alignments pass through areas with trees and tall shrubs, vegetation would be converted to short-statured shrubs and herbaceous vegetation. In addition, the long-term presence of structures above vegetation would reduce the amount of water the vegetation receives from precipitation. Finally, elevated structures with low clearance (generally, less than 15 feet) would limit sunlight. In some areas, short-statured shrubs and herbaceous vegetation cleared from beneath such structures and allowed to grow back may not grow back. The presence of elevated structures would preclude the development of mature forest habitat in these areas, reducing the potential for the recruitment of LWD to nearby streams. Because the elevated structures would be relatively narrow (typically 20 to 30 feet wide), oriented north to south, and generally more than 15 feet above the ground surface, shading impacts on riparian vegetation would be limited in most areas.

Sound Transit would use native vegetation to replant areas temporarily disturbed by construction. At sites where riparian zones are currently dominated by non-native species, the reintroduction of native vegetation could lead to long-term improvements in riparian habitat conditions.

Water Quality/Quantity

The development of any project alternatives would entail the creation of new impervious surfaces and the replacement of existing impervious surfaces. New impervious surfaces would include maintenance buildings, parking areas, tracks, train storage areas, and roadways. These new surfaces would replace a mix of existing impervious and pervious surfaces at each site. Impervious surfaces are associated with negative effects on receiving waters, affecting water quality and flow regimes, which in turn can have negative effects on aquatic life and aquatic habitat.

The sites proposed for the Preferred and South 344th Street alternatives currently include large amounts of pollution-generating impervious surfaces (PGIS), primarily parking lots and access roads. Some of these areas were developed before recent stormwater management requirements were in place, which results in stormwater runoff currently receiving little or no detention or treatment. Development of an operations and maintenance facility at either of the sites proposed for the Preferred and South 344th Street alternatives would replace some existing untreated PGIS with landscaping or other surfaces that are not pollution-generating.

Under any of the build alternatives, runoff from impervious surfaces created or replaced for construction and operation of OMF South would be detained and/or treated, as appropriate, in accordance with the Sound Transit Design Criteria Manual. Depending on the location of the project facilities, this would entail compliance with the city of Kent stormwater manual, the city of Federal Way addendum to the King County Surface Water Design Manual, the King County Surface Water Design Manual, and the WSDOT Highway Runoff Manual.

Appropriate treatment of runoff from PGIS would reduce the concentration of contaminants that enter receiving waters. However, water that passes through stormwater management facilities still contains contaminants (albeit in reduced concentrations) that can harm fish in receiving waters. These impacts could extend a considerable distance downstream, potentially affecting fish (including ESA-listed species) in stream reaches outside of the study area. In addition, during major storm events, the capacity of those facilities may be exceeded, and some runoff may enter streams and other surface waters without receiving treatment. It is important to note that the first-flush runoff from such events (i.e., that with the highest concentrations of contaminants) would enter treatment facilities. Bypassing would occur later in the storm event, after most contaminants have washed off.

The following is a discussion of an emerging contaminant of concern known as 6PPD-quinone. This chemical compound is a breakdown product resulting from the interaction of new car tires with ozone. Recent research has found 6PPD-quinone, a contaminant found in runoff from highways or roadways, to be a major contributor to pre-spawning mortality in adult coho salmon (Tian et al. 2021). The exposure and mortality of adult coho can be linked to both the sensitivity of coho salmon and the overlap of spawn timing with first flush events. The effects of this contaminant on ESA-listed Chinook salmon, steelhead, and bull trout are still being studied, but some of the early studies indicate that first-flush storm events are also lethal to juvenile coho, steelhead, and Chinook salmon (French et al. 2022). However, the concentration at which 6PPD-quinone in stormwater may have toxic effects on those species is still being evaluated. Given that juvenile steelhead and coho, in particular, typically spend more than 1 year rearing in natal streams, it is likely that exposure and mortality is occurring but undocumented thus far in the wild. Research has shown that in addition to juvenile coho, both juvenile steelhead (*Oncorhynchus mykiss*) and juvenile Chinook salmon (*O. tshawytscha*) are also vulnerable to untreated stormwater containing 6PPD-quinone; however, the effects are not as immediate, and instead of mortality occurring within a few hours of exposure (up to 4 hours for coho salmon), it can take 1 or 2 days for the juvenile steelhead and Chinook salmon to display mortality (French et al. 2022). A recent study looked at the sensitivity of early life stage (approximately3- weeks post swim-up [newly feeding] coho salmon and Chinook salmon) and found that juvenile coho salmon are three orders of magnitude more sensitive to 6PPDquinone than Chinook salmon (Lo et al. 2023). This study found a 7.1 percent survival for coho salmon exposed to the lowest concentration treatment group, while Chinook salmon showed 61.4 percent survival in the highest concentration treatment group (Lo et al. 2023). While not showing the degree of sensitivity to stormwater runoff containing 6PPD-quinone as coho salmon, juvenile steelhead and Chinook do appear to exhibit direct mortality, although at higher concentrations and with longer response times (Tian et al. 2021; French et al. 2022; Lo et al. 2023; and Brinkman et al. 2022).

Other harmful contaminants in stormwater runoff include polycyclic aromatic hydrocarbons, which have been found to cause reduced growth, increased susceptibility to infection, and increased mortality in salmonids (Meador et al. 2006; Varanasi et al. 1993). Another common component of stormwater runoff is copper, which can impair the olfactory system of salmonids and hinder their predator avoidance behavior (Sandahl et al. 2007).

Ecology has evaluated the effectiveness of stormwater facilities in providing treatment that prevents or reduces the toxicity of contaminants in receiving waters (Ecology 2022). Under any of the build alternatives, treatment effectiveness would be key consideration in the selection and design of stormwater management facilities. Stormwater ponds or a combination of vaults and ponds, may be considered to provide effective treatment. Construction of stormwater ponds could result in additional impacts on streams. For example, if ponds are located in vegetated stream buffers, pond construction could result in the temporary or permanent degradation of riparian habitat. Also, the siting needs for stormwater ponds could affect the locations of reconfigured stream channels.

Because the volume of runoff from impervious surfaces would be managed in accordance with local, state, and federal requirements, none of the alternatives would be expected to have long-term adverse effects on flow regimes in streams. Peak stream flows would not increase because the stormwater systems built for the proposed project would be designed to simulate predevelopment hydrology. Additional measures to reduce stormwater runoff, such as low-impact development or other on-site measures, would be considered at a more advanced phase of project development. Based on the above, none of the alternatives would be expected to have adverse effects on aquatic species and habitat as a result of altered peak or base flows.

Nighttime Lighting

Operation of OMF South and associated mainline or test tracks is not expected to result in any increases in nighttime illumination of fish-bearing waters (which could increase the risk of predation on juvenile salmonids) for several reasons. First, there are no fish-bearing waters within 200 feet of any of the OMF South project alternatives, including the mainline tracks. Even if downstream fish passage barriers are removed and access is restored, operation of the mainline and test tracks would not illuminate any surface waters because the tracks would have no overhead lighting and the train headlights would be directed parallel to the tracks. Finally, at the OMF South alternative sites, the potential for adverse effects under that future scenario would be avoided or minimized through the implementation of conservation measures for luminaires installed near surface-flowing waters, regardless of the waters' current fish-bearing status. Any luminaires within 50 feet of such waters would be shielded and directed away from the water's surface.

4.1.2.1 Preferred Alternative

Approximately 3,050 to 3,100 linear feet of surface-flowing stream fall within the permanent impact footprint for the Preferred Alternative. The affected stream segments would include approximately 2,450 to 2,500 linear feet of East Fork Hylebos Tributary (depending on whether the 40 mph Alignment or 55 mph Design Option is selected; see below) and approximately 600 linear feet of West Fork Hylebos Tributary (Table G3.4-1). As a result, this alternative would have a greater impact on aquatic habitats than either the Midway Landfill Alternative or the South 344th Street Alternative. Compared to the South 344th Street Alternative (which would affect 2,850 to 2,900 linear feet of streams overall), the Preferred Alternative would affect approximately 400 fewer linear feet of East Fork Hylebos Tributary. But this alternative would impact West Fork Hylebos Tributary, whereas the South 344th Street Alternative would avoid those impacts. Compared to the South 344th Street Alternative, the Preferred Alternative would realign less of East Fork Hylebos Tributary and would not daylight the section near S 344th Street. These impacts are discussed below.

East Fork Hylebos Tributary

Approximately 2,450 linear feet of East Fork Hylebos Tributary (surface-flowing) fall within the permanent impact footprint of this alternative. The affected portion of the stream extends from north of S 336th Street to S 344th Street (Figure G3.4-3). Approximately 1,650 feet of the stream channel in this area would be relocated and realigned. The interim design includes meanders and other features to enhance the availability and diversity of aquatic habitats. Based on the interim design, the addition of meanders would increase the length of the stream channel in this area by approximately 130 linear feet. The actual layout of the stream channel would be developed by the design-build contractor in consultation with Sound Transit, permitting agencies, and other stakeholders. Approximately 350 feet of the stream relocation would occur in the site footprint, and approximately 1,300 feet would be associated with the mainline tracks. The relocated stream channel would be approximately 40 to 70 feet west of the mainline tracks.

Currently, much of East Fork Hylebos Tributary in this area is confined within a straight and narrow channel that lacks complexity. Relocating and realigning the channel could create opportunities to add sinuosity and habitat complexity, potentially improving in-stream habitat conditions in some reaches. LWD would be placed in and near the stream channel to provide additional habitat complexity. The new channel would be designed to maintain flows and water quality conditions. An approximately 500-foot-long segment of the stream between the OMF site and I-5 would be within the permanent impact footprint but would not be relocated. The interim design shows the stream remaining in its existing channel in this area, approximately 70 feet west of the mainline tracks. Two lead track segments would come within approximately 30 to 40 feet of the stream near the northern and southern ends of this segment. Long-term impacts to this stream segment would be associated with reductions in the width of the vegetated riparian zone, as described below.

The interim design indicates that some of the relocated channel would be routed through a parcel immediately south of the Christian Faith Center property. That parcel is currently unvegetated and is used for storage of heavy equipment and construction materials. Under current conditions, the length of the stream channel in the area between that parcel and I-5 is approximately 320 feet, and the vegetated riparian area is confined to an approximately 80-foot-wide strip. Upon project completion, the length of the stream channel in that area would be approximately 380 feet, and the width of the area between the OMF site and the mainline tracks would be approximately 200 feet. It is assumed for this analysis that trees and other woody vegetation would be planted in all allowable areas between the OMF site and the mainline tracks. As a result, a wider area would be available to support riparian functions, but those functions would be limited in some parts of that area because trees and other tall vegetation would not be allowed to grow near the mainline tracks and the crossing that goes over one lead track segment in this area.

Although relocating and realigning the stream channel would have some beneficial effects, changing the physical characteristics of the stream could adversely affect its hydrology and downstream sediment regimes. In addition, the presence of the OMF site to the west and the mainline tracks to the east would further reduce the width of the already limited area available to support riparian functions. From S 336th Street to the southeastern corner of the Christian Faith Center property (a straight-line distance of approximately 0.25 mile), the vegetated riparian zone between the OMF site and the mainline tracks would be approximately 180 feet wide. Compared to the existing width of the vegetated riparian zone in this area (200 to 300 feet), this zone would amount to a 10 to 40 percent reduction in the width of the vegetated riparian zone along approximately 1,400 linear feet of stream channel. Riparian functions in this area would be further reduced by the presence of two lead track segments crossing the stream; trees and other tall vegetation would not be allowed to grow near the lead tracks.

Farther south, the stream would be confined to an approximately 80-foot-wide corridor between the Ellenos Yogurt parcel and I-5. This area would include about 400 linear feet of stream channel. Much of the stream in this area would be beneath or immediately adjacent to the mainline or lead tracks. The presence of support columns near the stream would constrain options for natural or human-created modifications to channel configuration in the future. In addition, existing forested riparian vegetation would be cleared and replaced with lower-growing vegetation or converted to hard surfaces, substantially reducing riparian functions along this stream segment.

Downstream of the Ellenos Yogurt parcel, the realigned channel would tie into the channel that would be daylighted as part of the Preferred Alternative. Under this alternative, approximately 420 linear feet of East Fork Hylebos Tributary immediately north of S 344th Street would be removed from a culvert and restored to a daylighted channel (Table G3.4-1). Downstream of the daylighted channel, the stream would be conveyed under the 21st Avenue S extension and S 344th Street in a new structure that would replace the existing, approximately 315-foot-long culvert. The new structure would be designed and installed in accordance with WDFW’s Water Crossing Design Guidelines (Barnard et al. 2013). Under current conditions, the stream is conveyed through this area in a 4-foot-diameter corrugated steel pipe that is not considered to be a barrier to fish passage.

The permanent stream buffer impact areas (Table G3.4-1) reflect the assumption that all of the existing forested riparian habitat along the affected stretch of stream would be cleared for construction. It may be possible to retain existing vegetation (including riparian forest) in some areas; the actual extent of riparian clearing and planting would be determined by the design-build contractor in consultation with Sound Transit. Where safety constraints allow, riparian areas for construction would be restored with native vegetation, with an emphasis on trees and shrubs. As discussed in Section 2.4.4, trees and other tall vegetation would not be allowed to grow back near the mainline tracks, lead tracks, test tracks, and associated facilities. In those areas, some riparian habitat functions would be restored through revegetation with native shrubs and other low-growing species. In areas where mixed deciduous and coniferous forest is replaced with project features and non-forested vegetation, the capacity of those areas to support riparian functions for East Fork Hylebos Tributary would be permanently reduced.

In addition, the 55 mph Design Option at the northern end of the mainline tracks would affect approximately 50 linear feet more of East Fork Hylebos Tributary than would the 40 mph Alignment (Table G3.41). The 55 mph Design Option would intersect the northern end of the stream in Belmor; the 40 mph Alignment would avoid it altogether.

West Fork Hylebos Tributary

Construction and operation of the Preferred Alternative would also affect aquatic and riparian habitats associated with West Fork Hylebos Tributary. The impacts on aquatic habitats in this area are difficult to quantify because the stream lacks a defined channel where it flows through Wetland WFW-02 and an associated in-line stormwater detention facility south of S 336th Street. For this reason, the estimated extent of project-related impacts is based on the linework obtained from the King County iMap interactive mapping tool. That source identifies approximately 600 linear feet of the stream that would fall within the permanent impact footprint of the Preferred Alternative.

Frontage improvements along S 336th Street to meet city standards would necessitate the installation of a longer crossing structure where West Fork Hylebos Tributary is crossed by the road. If the existing culverts at S 336th Street are replaced, the replacement structure or structures would be designed and installed in accordance with WDFW’s Water Crossing Design Guidelines (Barnard et al. 2013). The existing culverts are owned by the city of Federal Way and identified partial barriers to fish passage (WDFW ID# 933224).

The interim design proposes a single, approximately 19-foot-wide, 89-foot-long fish-passable structure to replace the existing culverts. If a structure with these dimensions is included in the final project design, the replacement structure would be longer than the existing, 86-foot-long culverts, reducing the length of surface-flowing stream channel. However, replacing two 42-inch-diameter pipes with a single, 19-foot-wide crossing structure would allow the stream to maintain a more natural channel width through the crossing. This, in turn, would help restore the hydrological capacity at the crossing site, allowing sediment and organic debris to pass through and providing fish unhindered passage beneath the roadway.

The extension of 18th Place S in a portion of Wetland WFW-02 would reduce the area of the stormwater pond/wetland complex through which the stream flows. The construction of this road extension and bike/pedestrian pathway would place fill in the wetland boundary and construct retaining walls in the eastern portion of the wetland. In addition, frontage improvements along S 336th Street could necessitate fill in the northern portion of the wetland, further reducing the extent of the wetland area that supports riparian functions for West Fork Hylebos Tributary. Impacts to wetland area and functions are described in Section 4.3, and potential measures for mitigating wetland impacts are found in Section 5.

Vegetation in and around Wetland WFW-02 supports riparian functions for West Fork Hylebos Tributary. The wetland and its buffer are dominated by forest that provides high-quality riparian habitat. Clearing of these forested areas for extending 18th Place S would permanently reduce their capacity to support riparian functions. See Section 4.3.2 for additional discussion of impacts to this wetland.

4.1.2.2 South 344th Street Alternative

The South 344th Street Alternative would affect approximately 2,850 to 2,900 linear feet of surface-flowing stream (Table G3.4-1). Compared to the Preferred Alternative, this alternative would affect approximately 400 more linear feet of the surface-flowing channel of East Fork Hylebos Tributary; however, impacts on West Fork Hylebos Tributary would be avoided altogether (Figure G3.4-4 and G3.4-5).

Impacts on East Fork Hylebos Tributary between S 336th Street and the culvert upstream of the WSDOT stormwater facility would be the same as described above for the Preferred Alternative. South of S 344th Street, approximately 400 linear feet of stream channel would fall within the permanent impact footprint of this alternative. In total, approximately 1,250 feet of the stream impacts would occur in the site footprint, and approximately 1,600 feet would be associated with the mainline tracks (Table G3.4-1). In contrast to the Preferred Alternative, this alternative would not involve the relocation of a short segment of this stream north of S 336th Street. As a result, this alternative would entail 1,650 linear feet of stream relocation impacts, compared to 1,700 linear feet under the Preferred Alternative.

Similar to the Preferred Alternative, the loss of mature, mixed deciduous and coniferous forest would reduce the riparian functions along the affected stream reaches. By affecting reaches downstream of S 344th Street, this alternative would degrade riparian habitat along 400 more feet of the stream than would the Preferred Alternative.

Under this alternative, approximately 420 linear feet of East Fork Hylebos Tributary immediately north of S 344th Street would be removed from an existing culvert and restored to a daylighted channel (Table G3.4-1). Daylighting this segment would increase the amount of functioning aquatic and riparian habitat available in the stream system.

Emergency vehicle access to the mainline tracks would be needed near the location of the daylighted stream segment. One of the options under consideration may require approximately 60 feet of channel that is currently culverted (and would otherwise be daylighted, as described above) to be placed in a new crossing structure. Because this alternative would not include the extension of 21st Avenue S, the replacement crossing structure south of the daylighted channel would be shorter, compared to the Preferred Alternative. If a culvert is needed, it would be designed using the stream simulation methodology outlined in WDFW’s Water Crossing Design Guidelines (Barnard et al. 2013), avoiding the potential creation of a barrier to fish passage. It may be possible to eliminate the need for a culvert through detailed design of the access and of the stream meanders. The design of the emergency vehicle access would need to be coordinated and approved by Sound Transit, WSDOT, and the city of Federal Way.

As with the Preferred Alternative, the 55 mph Design Option at the northern end of the mainline tracks would affect slightly more of East Fork Hylebos Tributary than would the 40 mph Alignment. The direct permanent impacts of the tail track design options on streams would be largely identical. The I-5 alignment would affect more stream/wetland buffer along East Fork Hylebos Tributary than would the Enchanted Parkway alignment (Table G3.4-1).

4.1.2.3 Midway Landfill Alternative

The Midway Landfill Alternative would have no direct impact on streams or stream channels because no streams are present on the Midway Landfill Alternative site. The closest mapped extent of North Fork McSorley Creek is approximately 2,000 feet west of the Midway Landfill Alternative and SR 99. The only project features affecting streams under this alternative relate to stormwater runoff and detention, as described below.

Compared to the other alternatives, the Midway Landfill Alternative would convert more vegetated areas to impervious land cover. It should be noted, however, that not all vegetated areas at the landfill function as pervious surfaces under current conditions. In reality, the surface of the landfill consists of grass on dense, compacted soils, underlain by an impermeable membrane cap. The landfill surface is designed to inhibit water from soaking through it. While the engineered multilayer membrane cap may have the capacity to attenuate some amount of runoff in the process, it prevents infiltration. Runoff is routed to an on-site surface water collection system. Thus, the area of grassy landfill cap converted to facilities such as maintenance buildings, parking areas, tracks, train storage areas, and roadways may not be representative of the area of pervious surfaces being converted to impervious surfaces. Nevertheless, based on the total size of the OMF site, the Midway Landfill Alternative would create the greatest amount of new pollution-generating impervious surfaces among the alternatives (see Table G3.4 3).

All stormwater runoff from the Midway Landfill Alternative site would be detained and treated in an underground vault system that would be designed in accordance with the city of Kent Stormwater Manual. The treatment vaults in turn would likely discharge to the on-site regional stormwater treatment and detention facility, which ultimately discharges to the North Fork McSorley Creek approximately 1.1 miles west of the Midway Landfill Alternative. The regional facility has been approved by both WDFW and Ecology. Treated stormwater that is discharged from the vaults would be directed to the regional treatment facility, where it would receive additional detention and treatment. As a result, an increase in the amount of impervious surfaces under this alternative would not be expected to adversely affect fish resources, stream hydrology, or aquatic habitat.

4.1.3 Construction Impacts

Temporary, construction-related impacts on aquatic resources would occur where stream buffers are affected by clearing and ground-disturbing work but are revegetated following construction. Such areas are within the project limits (including temporary construction easements) but not within the permanent footprint of the proposed facilities (including lead, test, and mainline tracks). The duration of such impacts would vary, depending on the existing condition of the affected area. Where clearing affects low-growing vegetation (e.g., grasses, herbaceous species) or invasive species, the riparian functions of the disturbed areas would likely be restored within one growing season of clearing and replanting. Where invasive species are cleared and replaced with native species, riparian functions may be improved. In contrast, temporary impacts on woody vegetation generally last longer because trees and/or shrubs may require several years or decades to achieve the size and stature necessary to provide pre-construction functions such as shade and LWD recruitment.

In addition to impacts on riparian vegetation, temporary impacts on stream habitats would occur if streams were diverted or placed in temporary pipes. Also, ground-disturbing work and equipment use in or near surface-flowing waters would present the risk of delivering sediment or contaminants (e.g., fuel, hydraulic fluids) to streams, temporarily degrading water quality. As discussed in Section 2.4.4, Analysis Assumptions, the estimated extent of areas that would be temporarily affected by project construction is based on mapping provided by the project design team.

The following sections outline the range of potential temporary construction impacts that could occur for each alternative. Actual impacts would depend on the selected alternative's final configuration and design, construction footprint and methods, BMPs implemented during construction (see Section 5.1.1, Avoidance and Minimization During Design Development, and Section 5.1.2, Construction Best Management Practices), and performance of post-construction restoration. Direct construction impacts would be identified and quantified during the final design and permitting of the Preferred Alternative. Although detailed construction limits have not yet been defined at this phase in the project design, potential project construction limits have been estimated (see Section 2.4.4, Analysis Assumptions). These impact areas are summarized in Table G3.4-2 and would be in addition to the long-term direct impacts.

4.1.3.1 Preferred Alternative

Most impacts to aquatic resources associated with the Preferred Alternative, including lead, test, and mainline tracks, would be long-term and are discussed in Section 4.1.2, Long-Term Impacts. Approximately 500 linear feet of East Fork Hylebos Tributary would fall within the temporary impact footprint (250 linear feet in the facility site and 250 feet along the mainline tracks; see Table G3.4-2). Impacts would include temporary loss of riparian habitat function and an elevated risk of water quality degradation, as described above. Site construction would temporarily affect approximately 1.4 acre of stream buffer habitat along East Fork Hylebos Tributary, and mainline track construction would affect approximately 2.2 acres.

Similar to permanent impacts, direct temporary impacts on West Fork Hylebos Tributary are difficult to quantify because the stream lacks a defined bed and bank in most of the study area. As with the analysis of permanent impacts, the estimated extent of project-related impacts is based on the linework obtained from the King County iMap interactive mapping tool. No parts of the line representing West Fork Hylebos Tributary south of S 336th Street fall within the temporary impact footprint of the Preferred Alternative. North of S 336th Street, approximately 50 linear feet of the mapped stream channel fall within the temporary impact footprint. Project construction is anticipated to have temporary impacts on the stream, such as temporary loss of riparian habitat function and an elevated risk of water quality degradation, as described above. During construction of frontage improvements along S 336th Street and installation of a replacement structure where the stream is crossed by the road, a small segment of the stream would likely be placed in a temporary bypass while construction is underway.

Vegetation in and around Wetland WFW-02 supports riparian functions for West Fork Hylebos Tributary. As with the analysis of permanent impacts, temporary impacts on the stream buffer in that area are identified for this analysis as the extent of temporary impacts on Wetland WFW-02 (approximately 2.7 acres). An additional 0.2 acre of this stream's buffer north of S 336th Street (i.e., outside of Wetland WFW-02) also fall within the temporary impact footprint.

The temporary impact footprint of the 55 mph Design Option at the northern end of the mainline tracks would overlap approximately 100 linear feet more of East Fork Hylebos Tributary than would the 40 mph Alignment (Table G3.4-2).

Table G3.4-2 Potential Temporary (Construction-Related) Impacts on Aquatic Resources

Alternative	Design Option	Project Element	Stream[1]	Stream Impact (linear feet)[2]	Total Stream Impact per Alternative	Stream Buffer Impact (acres)[3]	Total Stream Buffer Impact per Alternative (acres)
Preferred	40 mph Alignment	Site	East Fork Hylebos Tributary	250	550	1.4	3.8
			West Fork Hylebos Tributary[4]	50		2.9	
		Mainline[5]	East Fork Hylebos Tributary	250		2.2	
	55 mph Design Option	Site	East Fork Hylebos Tributary	250	650	1.4	7.2
			West Fork Hylebos Tributary[4]	50		2.9	
		Mainline[5]	East Fork Hylebos Tributary	350		2.9	
South 344th Street	40 mph Alignment and Enchanted Parkway Tail Track Alignment	Site	East Fork Hylebos Tributary	50	900	0.1	4.4
		Mainline[5]		850		4.3	
	55 mph Design Option and I-5 Tail Track Alignment	Site	East Fork Hylebos Tributary	50	1,050	0.1	4.7
		Mainline[5]		1,000		4.6	
	55 mph Design Option and Enchanted Parkway Tail Track Alignment	Site	East Fork Hylebos Tributary	50	1,050	0.1	5.1
		Mainline[5]		1,000		5.0	
	40 mph Alignment and I-5 Tail Track Alignment	Site	East Fork Hylebos Tributary	50	900	0.1	3.9
		Mainline[5]		850		3.8	
Midway Landfill	N/A	N/A	N/A	0	0	0	0

Notes:

(1) Both affected streams are Type F, per WAC 222-16-030.

(2) Includes the total length of surface-flowing stream within the construction-related impact footprint defined for this analysis.

(3) Values presented in this table represent all affected areas inside functional stream buffers, including areas that overlap with wetland buffers.

(4) The portion of this stream in the study area lacks a defined bed and bank where it flows through Wetland WFW-02. Direct impacts on the stream are considered permanent and are discussed above. Temporary impacts on the stream buffer are calculated as on the affected area of Wetland WFW-02, plus the area of temporary impacts on the stream's buffer north of S 336th Street. See text for further discussion.

(5) If neither the Preferred nor the South 344th Street alternative is selected, the mainline could be built later in time if TDLE is constructed as proposed. TDLE is currently under environmental review.

4.1.3.2 South 344th Street Alternative

Mainline construction for the South 344th Street Alternative would temporarily affect between approximately 850 and 1,000 linear feet of East Fork Hylebos Tributary, depending on the design option (Table G3.4-2). Impacts would include temporary loss of riparian habitat function and an elevated risk of water quality degradation, as described above. Site construction would temporarily affect approximately 0.1 acre of stream buffer habitat along East Fork Hylebos Tributary, and mainline track construction would affect approximately 3.8 to 5.0 acres, depending on the design option. This alternative would have no temporary impacts on West Fork Hylebos Tributary.

As with the Preferred Alternative, the 40 mph Alignment at the northern end of the mainline tracks would have a smaller construction-related impact on the northern end of East Fork Hylebos Tributary, compared to the 55 mph Design Option (Table G3.4-2). The direct temporary impacts of the tail track design options on streams would be identical. The Enchanted Parkway alignment would affect approximately 0.4 acre more stream/wetland buffer along East Fork Hylebos Tributary than would the I-5 alignment (Table G3.4-2).

4.1.3.3 Midway Landfill Alternative

The Midway Landfill Alternative would have no construction-related impacts on aquatic resources.

4.2 Vegetation, Wildlife, and Wildlife Habitat

Construction and operation of OMF South could adversely affect vegetation and terrestrial wildlife. Analyses in this subsection address the potential long-term and construction-related impacts of each alternative on vegetation, wildlife, and wildlife habitat. All the project alternatives are near existing highways and commercial, institutional, or industrial areas and have relatively disturbed habitats compared to less-developed sites in rural areas. Despite the overall matrix of sparse ecosystem resources in the study area, remnant patches of natural vegetation may provide travel corridors or islands of habitat, allowing some wildlife populations to persist in the urban landscape. Actual impacts would depend on final alternative selection and design, construction footprint and methods, BMPs implemented during construction (see Section 5.1.1, Avoidance and Minimization During Design Development, and Section 5.1.2, Construction Best Management Practices), and performance of post-construction restoration, including revegetation of disturbed areas and mitigation measures for areas protected under local critical areas ordinances.

As discussed in Section 3.2.3, Species and Habitats of Concern, no ESA-listed or state-listed plant or wildlife species are known or expected to be present in the study area. Similarly, WDFW (2022) does not identify any documented occurrences of state priority species in the study area. Forested areas, however, may provide suitable habitat for some priority species. Reductions in the amount of the forested cover type could have adverse effects on those species.

The only priority habitats known or expected to be present in the study area are mature forests, wetlands, and riparian areas. Potential impacts on mature forests are discussed in the following subsections. Potential impacts on wetlands are analyzed in Section 4.3, Wetlands. Potential impacts on riparian areas are analyzed in Section 4.1, Aquatic Species and Habitat.

4.2.1 No-Build Alternative

Under the No-Build Alternative, impacts to vegetation, wildlife, and wildlife habitat from construction or operation of OMF South would not occur. However, for the purposes of this technical report, the No-Build Alternative assumes that by the design year 2042, all planned Sound Transit 3 projects, including FWLE and TDLE, are built along with the other public and private projects planned within the study area. TDLE overlaps with the OMF South Preferred and South 344th Street alternatives. If TDLE is constructed as proposed, the mainline track associated with these OMF alternatives would be built later in time. Impacts associated with construction of the mainline track are addressed within the build alternatives impacts discussion below. All other TDLE-related impacts are addressed in Section 4.5, Cumulative Impacts.

4.2.2 Long-Term Impacts

Potential direct long-term impacts would occur where project construction converts vegetation or other wildlife habitat features to project facilities (including lead, test, and mainline tracks). Noise, light, and human activity associated with the operation of OMF South may also have long-term impacts on wildlife. These potential effects are described in greater detail below. Impacts associated with each alternative are discussed in the subsections that follow.

Vegetation Removal and Habitat Alteration

Any of the project alternatives would affect vegetation and wildlife, including species of concern, through the loss or degradation of habitat. Existing vegetation in the project footprint would be removed and replaced with tracks, buildings, parking lots, and other impervious surfaces. Table G3.4-3 presents a comparison of the project alternatives’ potential impacts on vegetation in the study area, based on the amount of each land cover type in the permanent impact footprint. The geographic distribution and configuration of impact areas are depicted in Figures G3.4-7 through G3.4-12.

As discussed in Section 2.4.4, Analysis Assumptions, The impact values and areas in the table and figures represent conservative estimates of the impacts of the alternatives. Not all areas within the project footprint would be converted to structures or hard surfaces. Actual anticipated impacts would be determined when an alternative is selected to be built and the project design is sufficiently advanced to undergo permitting review.

The impacts of project operation on vegetation and wildlife habitat would vary, depending on the affected land cover type. In much of the study area (e.g., in areas classified as the Commercial or Residential land cover types), the replacement of existing impervious surfaces and structures would constitute a minimal change in ecological functions such as the capacity to support wildlife.

The severity of impacts would be greater where cover types dominated by native or structurally complex vegetation (i.e., the mature native forest, other native forest, or wetland/stream cover types) are affected. Removing trees, snags, and understory vegetation would eliminate nesting and foraging sites for birds, roosting sites for bats, and hiding cover for small mammals. Alternatives that affect a greater area of such habitat types would have a higher likelihood of adverse effects on vegetation and wildlife.

The severity of impacts would also depend on the type of structure. Construction of the OMF site and at-grade segments of mainline tracks would mean the permanent removal of nearly all vegetation within the permanent impact footprint (although some vegetation would be allowed to grow in landscaped portions of the OMF site). In contrast, establishment and growth of vegetation would be possible underneath elevated structures that are high enough above the ground (generally 15 to 20 feet). Trees and other tall vegetation would not be allowed to grow near track segments, and vegetation that does grow underneath elevated structures would be limited by the reduced availability of sunlight and rainfall.

Table G3.4-3 Potential Long-Term Impacts on Vegetation

Alternative	Design Option	Land Cover Type									
		Commercial	**Residential**	**Grassland**	**Invasive Brush**	**Non native Forest**	**Mature Native Forest**	**Other Native Forest**	**Wetland/Stream**	**Stormwater Pond**	**Total(1)**

FIGURE G3.4-12
Impacts to Vegetation Cover
Midway Landfill Alternative

Noise, Light, and Human Disturbance

Operation of OMF South would entail moderate to high levels of human activity and associated noise and light. Notably, all three project alternatives are adjacent to I-5 and are in developed areas with relatively high levels of human activity. In addition to the noise, light, and vehicle traffic on the highway, regular human activity associated with residential, commercial, institutional, and industrial development is a common feature of the landscape throughout the study area. Wildlife that use habitats in or near the project alternatives are regularly exposed to human activity, noise, and light.

The extent of project-related impacts is based on changes in activity levels. The intensity of each alternative’s effects would depend on existing activity patterns and lighting regimes at the site under consideration; these differences are described in the discussions of individual alternatives, below. The potential for adverse effects would be greatest where facilities are constructed near important habitat areas, including forests, wetlands, and riparian areas.

Noise and human activity have been demonstrated to displace wildlife from occupied habitats and to disrupt normal behaviors (e.g., territorial singing of songbirds, mating and alarm calls of amphibians and small mammals, and foraging activities of raptors). Artificial night lighting can adversely affect wildlife by disrupting foraging behavior, circadian rhythms, and dispersal movements (including migration). Potential adverse effects associated with artificial lighting would be minimized through compliance with applicable local lighting standards and BMPs, such as screening and directing lights away from the night sky and nearby residential and natural areas.

If activity or noise levels at the maintenance facility noticeably exceed current conditions, affected animals may be displaced from otherwise suitable habitat, potentially leading to competition with animals that occupy suitable habitat at other sites with less disturbance. Such competition may produce increased stress and decreased reproductive success for affected individuals. Adverse behavioral responses to increased night lighting may have similar consequences. Animals displaced from areas of suitable habitat may be exposed to an elevated risk of predation or vehicle collisions while they are seeking new areas of suitable habitat. Based on the limited amount of area that would be affected under any of the alternatives, such effects would not be expected to measurably reduce the regional populations of any wildlife species. None of the project alternatives is within 0.25 mile of a known breeding area or other sensitive site for any wildlife species of concern.

4.2.2.1 Preferred Alternative

The extent of this alternative’s effects on the mature native forest, other native forest, and wetland/ stream cover types would be greater than the Midway Landfill Alternative and approximately equal to the South 344th Street Alternative. Under this alternative (with either design option), construction and operation of the facility, including lead, test, and mainline tracks, would result in permanent impacts on approximately 14 acres of mature native forest, 7 acres of other native forest, and 7 acres of the wetland/stream cover type (Table G3.4-3). Most impacts (11 of 14 acres) on the mature native forest cover type would be associated with the facility site rather than the mainline tracks. Approximately 5 acres of mature native forest habitat surrounding Wetland WFW-02 would fall within the permanent impact area of the facility, as would approximately 6 acres along the eastern edge of the facility. Approximately 3 acres of mature native forest habitat east of the facility would fall within the permanent impact area of the mainline tracks. The mainline tracks in this area would be on an elevated guideway, generally 20 to 30 feet above ground level. The lowest clearance would be about 14 feet above ground level, at a location approximately 350 feet south of S 336th Street.

Compared to the South 344th Street Alternative, the Preferred Alternative would affect less of the forested wetland and riparian habitats associated with East Fork Hylebos Tributary. The impacts of 55 mph Design Option at the northern end of the mainline tracks would be essentially identical to those of the 40 mph Alignment (see Table G3.4-3).

Based on the prevalence of the Commercial and Residential cover types in the surrounding study area (see Table G3.3-7), OMF South operations at the Preferred Alternative site would probably result in a less noticeable increase in human activity and associated noise and light, compared to the Midway Landfill Alternative. By affecting more areas of complex and native cover types, however, this alternative would likely degrade or eliminate more areas that currently provide resting and hiding cover for wildlife. As such, the potential for long-term behavioral disruption or displacement from suitable habitats may be greater under this alternative than under the Midway Landfill Alternative.

4.2.2.2 South 344th Street Alternative

The extent of the South 344th Street Alternative's effects on native and complex habitats would be similar to but lower than that of the Preferred Alternative. Differences between these two alternatives arise primarily from the exclusion of Wetland WFW-02 and surrounding forested areas from the impact area of the South 344th Street Alternative. Compared to the Preferred Alternative, this alternative would affect fewer acres of the mature native forest (10 acres, compared to 14) and wetland/stream (3 acres, compared to 7) cover types. This alternative would affect 5 to 6 more acres of other native forest than the Preferred Alternative, depending on the tail track design option. Similar to the Preferred Alternative, most of the impacts on mature native forest would be associated with the facility site, not the mainline tracks (Table G3.4-3).

The impacts of the 55 mph Design Option for the curve at the northern end of the mainline tracks would be essentially identical to those of the 40 mph Alignment (see Table G3.4-3). At the southern end of the facility, the design options for the tail tracks would have essentially identical impacts on the mature native forest and wetland/stream cover types, while the I-5 alignment would have slightly more impacts on other native forest, compared to the Enchanted Parkway alignment (see Table G3.4-3).

Based on the smaller extent of impacts on complex and native cover types (and the similar degree of existing development in the study area), this alternative would likely have a lower potential to disturb wildlife over the long term, compared to the Preferred Alternative.

4.2.2.3 Midway Landfill Alternative

Compared to the other project alternatives, the Midway Landfill Alternative would have minimal effects on native or complex habitats (i.e., the mature native forest, other native forest, and wetland/stream cover types). Most of the permanently affected area consists of the grassland cover type. Only 4 acres of other native forest would be affected, and no mature native forest or wetland/stream would be affected (Table G3.4-3), primarily because these cover types are not abundant at the Midway Landfill Alternative site (Table G3.3-6).

OMF South operations at the Midway Landfill site would result in a greater increase in human activity and associated noise and light, compared to the other build alternatives. This is because most of the site is currently fenced to limit access to the landfill. In contrast, the Preferred and South 344th Street alternative sites are surrounded by commercial and residential areas with relatively high levels of human activity under current conditions. Compared to the other two alternatives, however, the Midway Landfill Alternative would have a lower potential for adverse effects on wildlife, because it would affect fewer acres of structurally complex habitat types.

4.2.3 Construction Impacts

Construction-related impacts include temporary loss or degradation of terrestrial habitats, as well as disturbance due to construction-related noise, light, and human activity. Clearing for project construction would also increase the risk of contributing to the spread of noxious or invasive weed species. As discussed in Section 2.4.4, Analysis Assumptions, the estimated extent of areas that would be temporarily affected by project construction is based on mapping provided by the project design team.

Noxious weeds and invasive plants rapidly colonize disturbed sites, such as construction areas, preventing native species from becoming reestablished following ground disturbance. Noxious weeds and invasive plants also spread into undisturbed areas and provide poor habitat or forage for wildlife. Several of the BMPs that would be implemented during project construction are intended to avoid, reduce, and control new infestations of noxious weeds (see Section 5.1.1, Avoidance and Minimization During Design Development, and Section 5.1.2, Construction Best Management Practices). These BMPs would likely reduce but may not eliminate the potential for noxious weeds and invasive plants to colonize sites disturbed by construction. The risk of colonization would be proportional to the amount of area temporarily disturbed by construction: an alternative with a greater extent of ground disturbance would pose a higher risk of contributing to the establishment or spread of noxious weeds and invasive plants.

In disturbed areas, any of the project alternatives would provide the opportunity to, at least temporarily, reduce invasive species, such as Himalayan blackberry, through vegetation removal. In some areas, noxious weeds may be eradicated because cover types dominated by invasive species (e.g., Commercial, Invasive Brush) would be converted to maintenance facilities, landscaping, and other areas where invasive species would not be able to grow. In areas where invasive species are replaced with native species, construction-related impacts may result in improved habitat function.

The duration of temporary impacts would vary depending on the type of vegetation that is affected. Impacts on grasses and areas dominated by fast-growing invasive species would generally be short-lived, with functions typically returning to pre-impact levels within one growing season. In contrast, temporary impacts on woody vegetation generally last longer because trees and/or shrubs require several years or decades to achieve the size and stature necessary to provide pre-impact functions, such as canopy habitat.

The following sections outline the range of potential temporary construction impacts that could occur for each alternative. These impact areas are summarized in Table G3.4-4 and would be in addition to the long-term direct impacts described in Section 4.2.2, Long-Term Impacts. Actual impacts would depend on the final configuration and design of the Preferred Alternative, construction footprint and methods, BMPs implemented during construction (see Section 5.1.1, Avoidance and Minimization During Design Development, and Section 5.1.2, Construction Best Management Practices), and performance of post-construction restoration. Direct construction impacts would be identified and quantified during the final design and permitting of the Preferred Alternative.

Table G3.4-4 Potential Temporary (Construction-Related) Impacts on Vegetation

Alternative	Design Option	Land Cover Type									
		Commercial	Residential	Grassland	Invasive Brush	Non native Forest	Mature Native Forest	Other Native Forest	Wetland/Stream	Stormwater Pond	Total[1]
OMF Site Impacts (acres)											
Preferred	N/A	8	2	<0.5	1	<0.5	<0.5	1	<0.5	1	**13**
South 344th Street	N/A	1	0	<0.5	0	<0.5	<0.5	<0.5	<0.5	0	**1**
Midway Landfill	N/A	1	<0.5	2	2	0	0	1	0	<0.5	**7**
Mainline Impacts (acres)[2]											
Preferred	40 mph Alignment	13	6	2	3	0	2	6	<0.5	1	**33**
	50 mph Design Option	13	6	3	3	0	2	6	<0.5	1	**34**
South 344th Street	40 mph Alignment and Enchanted Parkway Tail Track Alignment	16	6	3	3	0	2	11	<0.5	1	**42**
	55 mph Design Option and I-5 Tail Track Alignment	17	6	5	3	0	2	10	<0.5	1	**42**
	55 mph Design Option and Enchanted Parkway Tail Track Alignment	16	6	5	3	0	2	11	<0.5	1	**43**
	40 mph Alignment and I-5 Tail Track Alignment	16	6	3	3	0	2	10	<0.5	1	**41**
Midway Landfill[3]	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A	**N/A**

Notes:

(1) The total values for some rows do not equal the sum of the values in the row due to rounding errors.

(2) If neither the Preferred nor the South 344th Street alternative is selected, the mainline could be built later in time if TDLE is constructed as proposed. TDLE is currently under environmental review.

(3) The Midway Landfill Alternative would not include any mainline or test track construction.

4.2.3.1 Preferred Alternative

The temporary impact footprint for this alternative includes a large amount of clearing at the northern end of the mainline tracks to accommodate staging, stockpiling, and other construction activities (Figure G3.4-7 and G3.4-8). Most of the affected area would consist of the commercial or residential cover types (Table G3.4-4).

The extent of temporary, construction-related impacts on the other native forest cover type would be less than that of the South 344th Street Alternative and greater than the Midway Landfill Alternative (Table G3.4-4). Nearly all temporary impacts on vegetation would be associated with construction of the mainline tracks, not the facility site. The associated potential for temporary loss or degradation of terrestrial habitats and disturbance of sensitive wildlife species during construction would thus be slightly lower than that of the South 344th Street Alternative. The temporary impacts of the Preferred Alternative and the South 344th Street Alternative on the mature native forest and wetland/stream cover types would be essentially identical. However, it may take several years for the forested vegetation communities and several decades for the mature forested communities to return to their preconstruction habitat function.

Based on the total extent of temporary, construction-related impacts, the risk of contributing to the establishment and spread of noxious weeds and invasive plants under this alternative would be slightly greater than that of the South 344th Street Alternative and substantially greater than that of the Midway Landfill Alternative.

The 40 mph Alignment would have a slightly larger area of temporary impacts, compared to the 55 mph Design Option. This difference reflects areas at the northern end of the connecting track segment that would be affected permanently under the 55 mph Design Option but only temporarily under the TDLE 40 mph Alignment. As such, the 40 mph Alignment would have a slightly higher potential for temporary loss or degradation of terrestrial habitats and disturbance of sensitive wildlife species during construction, as well as a slightly higher risk of contributing to the establishment and spread of noxious weeds and invasive plants.

4.2.3.2 South 344th Street Alternative

Similar to the Preferred Alternative, the temporary impact footprint for this alternative includes a large amount of clearing at the northern end of the mainline tracks to accommodate staging, stockpiling, and other construction activities. In addition, the temporary impact footprint for this alternative extends farther south than that of the Preferred Alternative, affecting areas around the I-5/SR 18 interchange (see Figure G3.4-10 and Figure G3.4-11). As a result, the total extent of temporary, construction-related impacts under the South 344th Street Alternative would be greater than either of the other build alternatives. As with the Preferred Alternative, most of the affected area would consist of the commercial or residential cover types (Table G3.4-4).

The extent of temporary, construction-related impacts on the other native forest cover type would be greater than that of the Preferred Alternative (Table G3.4-4), resulting in a greater temporary loss or degradation of terrestrial habitats and disturbance of sensitive wildlife species during construction. The temporary impacts of the South 344th Street Alternative and the Preferred Alternative on the mature native forest and wetland/stream cover types would be essentially equivalent.

The total extent of temporary, construction-related impacts – and the associated risk of contributing to the establishment and spread of noxious weeds and invasive plants – would be slightly less than that of the Preferred Alternative (Table G3.4-4).

The differences between the 40 mph Alignment and the 55 mph Design Option would be as described for the Preferred Alternative. At the southern end of the facility, the design options for the tail tracks would have essentially identical temporary impacts on the mature native forest and wetland/stream cover types, while the Enchanted Parkway alignment would have slightly more impacts on other native forest, compared to the I-5 alignment (see Table G3.4-4).

4.2.3.3 Midway Landfill Alternative

The extent of temporary, construction-related impacts would be substantially smaller under the Midway Landfill Alternative than under the other build alternatives (Table G3.4-4). Also, much less of the other native forest cover type (and no mature native forest or wetland/stream) is within the temporary impact area of this alternative, compared to the other two project alternatives. As such, this alternative would have the lowest potential for temporary loss or degradation of terrestrial habitats and disturbance of sensitive wildlife species during construction. Based on the small size of the temporary disturbance area, this alternative would have the lowest risk of contributing to the establishment and spread of noxious weeds and invasive plants.

4.3 Wetlands

Analyses in this subsection address the potential long-term and temporary (i.e., construction-related) impacts of each alternative on wetlands and wetland buffers. Actual impacts would depend on the location and final design of the project the Sound Transit Board of Directors selects to build, the construction footprint and methods, the BMPs implemented during construction (see Section 5.1.1, Avoidance and Minimization During Design Development, and Section 5.1.2, Construction Best Management Practices), and the performance of post-construction restoration.

To the extent that impacts cannot be avoided or minimized during the design process or reduced through BMPs, Sound Transit would implement additional measures to address adverse effects and provide compensatory mitigation measures where adverse effects are unavoidable. Sound Transit has committed to achieving no net loss of ecosystem function on a project-wide basis (Sound Transit 2007). As discussed in Section 5.3, Compensatory Mitigation, compensatory mitigation would be implemented in accordance with applicable federal, state, and local requirements and guidelines.

4.3.1 No-Build Alternative

Under the No-Build Alternative, impacts to wetlands from construction or operation of OMF South would not occur. However, for the purposes of this technical report, the No-Build Alternative assumes that by the design year 2042, all planned Sound Transit 3 projects, including FWLE and TDLE, are built along with the other public and private projects planned within the study area. TDLE overlaps with the OMF South Preferred and South 344th Street alternatives. If TDLE is constructed as proposed, the mainline track associated with these OMF alternatives would be built later in time. Impacts associated with construction of the mainline track are addressed within the build alternatives impacts discussion below. All other TDLE-related impacts are addressed in Section 4.5, Cumulative Impacts.

Construction of FWLE will temporarily affect the buffer of Wetland WL 148.67L in the Midway Landfill Alternative study area. Neither this wetland nor its buffer would be affected by any of the OMF South build alternatives.

4.3.2 Long-Term Impacts

Under any of the project alternatives, direct long-term impacts on wetland resources would occur where permanent features such as project facilities (including lead, test, and mainline tracks) overlap wetlands or wetland buffers.

Filling, excavating, or clearing within wetlands or wetland buffers would diminish wetland functions through the loss of area, changes to surface or subsurface water flows, or long-term changes to vegetation. Project actions that may entail such impacts include construction of buildings, roadways, mainline or lead tracks (including support columns), train storage areas, retaining walls, parking areas, and stormwater facilities.

Not all wetlands underneath elevated structures (e.g., lead, test, and mainline tracks) would be permanently filled. However, trees and other tall vegetation would not be allowed to grow near track segments. This would result in the permanent conversion from trees and tall shrubs to short-statured shrubs and herbaceous vegetation. In addition, the long-term presence of structures above vegetation would reduce the amount of sunlight and precipitation the plants receive, potentially making these areas more sparsely vegetated. Also, the interception of precipitation by overhead structures could have the potential for long-term impacts on wetland hydrology. For any given wetland, the severity of those impacts would depend on the proportion of the wetland that is affected, as well as the extent to which precipitation contributes to wetland hydrology at that site.

For these reasons, comparisons of the impacts of the alternatives are based on the overlap between any project features (including elevated structures) and wetlands or wetland buffers. In some cases (for example, where the impact area of an alternative would overlap a substantial proportion of a wetland), impacts that do not encompass an entire wetland may degrade wetland functions to such an extent that the entire wetland would be considered a loss. Such determinations would be based on professional judgment. If one of the action alternatives is selected, determinations of wetland losses would be part of the process of applying for permits and determining mitigation needs. Wetland impact areas are summarized in Table G3.4-5 and are depicted in Figures G3.4-1 through G3.4-6. Wetland buffer impacts are summarized in Table G3.4-6. Impacts associated with each alternative, including tabular summaries of impacts on individual wetlands, are discussed in the subsections that follow.

As discussed in Section 2.4.4, Analysis Assumptions, the impact values and areas in the table and figures represent conservative estimates of the impacts of the alternatives. Not all areas within the project footprint would be converted to structures or hard surfaces. Actual anticipated impacts will be determined when an alternative is selected to be built and the project design is sufficiently advanced to undergo permitting review.

Table G3.4-5 Potential Long-Term Wetland Impacts (acres)

Wetland Rating[1]	Alternative		
	Preferred	South 344th Street	Midway Landfill
OMF Site Impacts			
Category II Wetlands	1.8	0	0
Category III Wetlands	0.9	1.4	0
Total Site Impacts	*2.7*	*1.4*	*0*
Mainline Impacts[2, 3]			
Category III Wetlands	1.6	1.5	N/A[4]
Category IV Wetlands	<0.1	<0.1	N/A[4]
Total Mainline Impacts	*1.6*	*1.5*	*N/A[4]*
Total Impacts			
Total Impacts	***4.3***	***3.0***	***0***

Notes:

(1) Wetland ratings (Hruby 2014) are preliminary and subject to review by permitting authorities.

(2) Under either the Preferred Alternative or the South 344th Street Alternative, the impacts of the design options for the curve at the northern end of the mainline tracks would differ by 0.01 acre. Similarly, the impacts to wetlands of the tail track design options for the South 344th Street Alternative would differ by 0.01 acre. See text for details.

(3) If neither the Preferred nor the South 344th Street alternative is selected, the mainline could be built later in time if TDLE is constructed as proposed. TDLE is currently under environmental review.

(4) The Midway Landfill Alternative would not include any mainline or test track construction.

Table G3.4-6 Potential Long-Term Wetland Buffer Impacts

Alternative/Mainline Design Option		Wetland Buffer Impacts (acres)[1]	Affected Wetland Buffers
OMF Site Impacts			
Preferred		7.8	WFW-01, WFW-02, WFW-03, WFW-04, WFW-15
South 344th Street		6.3	WFW-01, WFW-03, WFW-04, WFW-06, WFW-11, WFW-13, WFW-15, WFW-17, WFW-18
Midway Landfill		0	N/A
Mainline Impacts[2]			
Preferred	With 40 mph Alignment	4.7	WFW-01, WFW-03, WFW-04, WFW-06, WFW-11, WFW-13, WFW-15, WFW-32
	With 55 mph Design Option	5.1	WFW-01, WFW-03, WFW-04, WFW-06, WFW-07, WFW-11, WFW-13, WFW-15
South 344th Street	With 40 mph Alignment and Enchanted Parkway Tail Track Alignment	7.0	WFW-01, WFW-03, WFW-04, WFW-05, WFW-06, WFW-11, WFW-13, WFW-15, WFW-17, WFW-32
	With 55 mph Design Option and I-5 Tail Track Alignment	7.2	WFW-01, WFW-03, WFW-04, WFW-05, WFW-06, WFW-07, WFW-11, WFW-13, WFW-15, WFW-17,
	With 55 mph Design Option and Enchanted Parkway Tail Track Alignment	7.2	WFW-01, WFW-03, WFW-04, WFW-05, WFW-06, WFW-07, WFW-11, WFW-13, WFW-15, WFW-17
	With 40 mph Alignment and I-5 Tail Track Alignment	7.0	WFW-01, WFW-03, WFW-04, WFW-05, WFW-06, WFW-11, WFW-13, WFW-15, WFW-17, WFW-32

Notes:

(1) Impact numbers presented in this table represent all affected areas inside functional wetland buffers, including areas that overlap with stream buffers; therefore, this table likely overestimates the extent of buffer impact areas. Stream areas, defined by the OHWL, are excluded from wetland buffer areas.

(2) If neither the Preferred nor the South 344th Street alternative is selected, the mainline could be built if TDLE is constructed as proposed. TDLE is currently under environmental review.

4.3.2.1 Preferred Alternative

The Preferred Alternative, including the mainline and test tracks, would have the greatest extent of long-term impacts on wetlands and wetland buffers among the project alternatives (Tables G3.4-5 and G3.4-6, Figures G3.4-1 through G3.4-3). Impacts on individual wetlands are shown in Table G3.4-7.

A large portion of the total wetland impact area (nearly 40 percent) would occur in Wetland WFW-02, a Category II forested wetland that is associated with West Fork Hylebos Tributary and an associated in-line stormwater facility in the northwestern portion of the proposed OMF South footprint. The extension of 18th Place S and the construction of a bike/pedestrian pathway to meet local code requirements would place fill within the wetland boundary and construct retaining walls in the eastern portion of the wetland. In addition, frontage improvements along S 336th Street could place fill in the northern portion of the wetland. These impacts would reduce wetland habitat, water quality, and hydrologic functions, as well as reducing wetland buffer functions. To minimize impacts to the wetland and its buffer, the roadway would be supported by a retaining wall. As discussed in Section 5.1.1, Avoidance and Minimization During Design Development, Sound Transit is exploring options to further avoid and minimize impacts on wetlands during the design development process, to the extent feasible.

Table G3.4-7 Potential Long-Term Impacts of the Preferred Alternative on Wetlands (acres)

Wetland ID	Wetland Rating[1]	OMF Site Impacts	Mainline Impacts[2]
WFW-01	III	0.9	0.6
WFW-02	II	1.8	0
WFW-03	III	0	0.3
WFW-04	III	<0.05	0
WFW-06	IV	0	<0.05
WFW-07[3]	III	0	<0.05
WFW-11	III	0	0.3
WFW-13	IV	0	<0.05
WFW-15	III	0	0.2
WFW-32[4]	IV	0	<0.05
TOTAL		**2.7**	**1.6**

Notes:

(1) Wetland ratings (Hruby 2014) are preliminary and subject to review by permitting authorities. See Table G3.3-8 for information about the size and rating of individual wetlands.

(2) Impacts for the mainline design options would differ slightly (notes #3 and #4 below). See text for details.

(3) Wetland WFW-07 would only be impacted by the 55 mph Design Option.

(4) Wetland WFW-32 would only be impacted by the 40 mph Alignment.

Most of the other wetlands that would be impacted by the Preferred Alternative are riverine wetlands associated with East Fork Hylebos Tributary (Wetlands WFW-01, WFW-03, WFW-07, and WFW-15). The largest of these is Wetland WFW-01, which lies entirely within the permanent impact footprint. A small portion (less than 0.05 acre) of Wetland WFW-07 would be intersected by the 55 mph Design Option for the curve at the northern end of the mainline track; the 40 mph Alignment would avoid long-term impacts on that wetland and its buffer altogether.

Wetlands east and adjacent to the site may be affected by lead tracks. With the possible exception of support columns for the lead tracks, no permanent structures would likely be placed within any of these wetlands, or within Wetland WFW-03, which would be affected by the southern tail tracks. Project related impacts would primarily be associated with vegetation clearing and the interception of sunlight and precipitation by overhead structures.

This alternative would have long-term impacts on the buffers of all the impacted wetlands identified in Table G3.4-7 (Table G3.4-6).

4.3.2.2 South 344th Street Alternative

The extent of long-term direct impacts on wetlands under the South 344th Street Alternative, would be less (3.0 acres) than under the Preferred Alternative (4.1 acres), primarily because the facility site would not impact Wetland WFW-02 (Table G3.4-5; impacts of this alternative on individual wetlands are shown in Table G3.4-8). The overall impacts of the mainline tracks on wetlands would be similar in scale to those of the Preferred Alternative but with some differences in impacts on individual wetlands. In addition to avoiding impacts on Wetland WFW-02, the South 344th Street Alternative would affect less of Wetland WFW-15 than would the Preferred Alternative. Conversely, the long-term impact footprint of this alternative would include three wetlands (WFW-05, WFW-17, and WFW-18) that would not be impacted by the Preferred Alternative. Wetlands WFW-01 and WFW-03 may be affected by lead tracks.

Table G3.4-8 Potential Long-Term Impacts of the South 344th Street Alternative on Wetlands (acres)

Wetland ID	Wetland Rating[1]	OMF Site Impacts	Mainline Impacts[2]
WFW-01	III	0.9	0.6
WFW-03	III	0	0.3
WFW-04	III	0.5	<0.05
WFW-05	III	0	0.1
WFW-06	IV	0	<0.05
WFW-07[3]	III	0	<0.05
WFW-11	III	0	0.3
WFW-13	IV	0	<0.05
WFW-15	III	0	<0.05
WFW-17	III	0	<0.05
WFW-18	III	<0.05	0
WFW-32[4]	IV	0	<0.05
Total Impacts		**1.4**	**1.6**

Notes:

(1) Wetland ratings (Hruby 2014) are preliminary and subject to review by permitting authorities. See Table G3.3-8 for information about the size and rating of individual wetlands.

(2) Impacts for the mainline design options would differ slightly (notes #3 and #4 below). The tail track design options for this alternative would have identical impacts on wetlands. See text for details.

(3) Wetland WFW-07 would only be impacted by the 55 mph Design Option.

(4) Wetland WFW-32 would only be impacted by the 40 mph Alignment.

This alternative would have permanent impacts on the buffers of all the wetlands identified in Table G3.4-8 (see Table G3.4-6).

The direct long-term impacts of the design options on wetlands would be essentially identical. As under the Preferred Alternative, the 40 mph Alignment would avoid long-term impacts on Wetland WFW-07 and its buffer, and the 55 mph Design Option would affect less than 0.05 acre of that wetland. Neither of the tail track options would have any direct impacts on wetlands, and their impacts on wetland buffers would be essentially identical (see Figures G3.4-4 and G3.4-5).

4.3.2.3 Midway Landfill Alternative

The Midway Landfill Alternative would have no long-term impacts on wetlands because there are no regulated wetlands or wetland buffers within the temporary or permanent impact footprints of this alternative (see Section 3.3.1.2, Midway Landfill Alternative).

4.3.3 Construction Impacts

Potential project construction limits have been estimated at this phase in the project design (see Section 2.4.4, Analysis Assumptions). Temporarily impacted wetlands and wetland buffers are shown in Figures G3.4-1 through G3.4-5 and summarized in Tables G3.4-9 and G3.4-10. Temporary impacts would be in addition to the long-term direct impacts described in Section 4.3.2.

Table G3.4-9 Potential Temporary (Construction-Related) Impacts on Wetlands

Wetland Rating[1]	Alternative		
	Preferred	**South 344th Street**	**Midway Landfill**
OMF Site Impacts			
Category II Wetlands	2.7	0	0
Category III Wetlands	0.3	0	0
Category IV Wetlands	<0.05	0	0
Total Site Impacts	*3.0*	*0*	*0*
Mainline Impacts[2, 3]			
Category III Wetlands	<0.05	0.3	N/A
Category IV Wetlands	<0.05	<0.05	N/A
Total Mainline Impacts	*0.1*	*0.3*	*N/A*[4]
Total Impacts			
Total Impacts	***3.0 - 3.1***[2]	***0.3***	***0***

Notes:

(1) Wetland ratings (Hruby 2014) are preliminary and subject to review by permitting authorities.

(2) Under either the Preferred Alternative or the South 344th Street Alternative, the impacts of the design options for the curve at the northern end of the mainline tracks would differ by less than 0.05 acre. For the Preferred Alternative, this difference causes the total impact area to round to 3.1 acres or 3.2 acres, depending on the design option. See text for details. The tail track design options for the South 344th Street Alternative would have identical impacts on wetlands.

(3) If neither the Preferred nor the South 344th Street alternative is selected, the mainline could be built if TDLE is constructed as proposed. TDLE is currently under environmental review.

(4) The Midway Landfill Alternative would not include any mainline or test track construction.

Table G3.4-10 Potential Temporary (Construction-Related) Impacts on Wetland Buffers

Alternative/Mainline Design Option		Wetland Buffer Impacts (acres)[1]	Affected Wetland Buffers
OMF Site Impacts			
Preferred		1.7	WFW-02, WFW-04, WFW-14, WFW-15, WFW-18, WFW-33
South 344th Street		0	N/A
Midway Landfill		0	N/A
Mainline Impacts[2]			
Preferred	With 40 mph Alignment	3.5	WFW-01, WFW-03, WFW-04, WFW-06, WFW-10a, WFW-11, WFW-12, WFW-13, WFW-15, WFW-16, WFW-32
	With 55 mph Design Option	4.1	WFW-01, WFW-03, WFW-04, WFW-06, WFW-07, WFW-10a, WFW-11, WFW-12, WFW-13, WFW-15, WFW-16, WFW-32
South 344th Street	With 40 mph Alignment and Enchanted Parkway Tail Track Alignment	3.9	WFW-01, WFW-03, WFW-05, WFW-06, WFW-10a, WFW-11, WFW-12, WFW-13, WFW-15, WFW-16, WFW-22, WFW-32
	With 55 mph Design Option and I-5 Tail Track Alignment	4.6	WFW-01, WFW-03, WFW-05, WFW-06, WFW-07, WFW-10a, WFW-11, WFW-12, WFW-13, WFW-15, WFW-16, WFW-22, WFW-32
	With 55 mph Design Option and Enchanted Parkway Tail Track Alignment	4.6	WFW-01, WFW-03, WFW-05, WFW-06, WFW-07, WFW-10a, WFW-11, WFW-12, WFW-13, WFW-15, WFW-16, WFW-22, WFW-32
	With 40 mph Alignment and I-5 Tail Track Alignment	4.0	WFW-01, WFW-03, WFW-05, WFW-06, WFW-10a, WFW-11, WFW-12, WFW-13, WFW-15, WFW-16, WFW-22, WFW-32

Notes:

(1) Values presented in this table represent all affected areas inside functional wetland buffers, including areas that overlap with stream buffers. Stream areas, defined by the OHWL, are excluded from wetland buffer areas.

(2) If neither the Preferred nor the South 344th Street alternative is constructed, the mainline could be built if TDLE is constructed as proposed. TDLE is currently under environmental review.

Temporary, construction-related impacts on wetland resources would occur where wetlands or wetland buffers are affected by clearing and ground-disturbing work but are restored following construction. Such areas are within the project limits (including temporary construction easements) but not within the permanent footprint of the proposed facilities (including lead, test, and mainline tracks). Temporary impacts may include temporary alteration of wetland area, soils, hydrology, and/or vegetation.

Temporary impacts on wetlands may result from the use of staging areas, temporary work areas, access roads, stream relocations, cofferdams, clearing, stockpiles, erosion and sediment controls, or other temporary structures necessary to complete construction of the permanent facilities. Construction-related dewatering may temporarily alter groundwater discharge to wetlands. Wetland and wetland buffer functions could also be impacted by soil compaction, accidental spills of hazardous substances, noise and other human-caused disturbances, sedimentation, and introduction of invasive species.

The duration of temporary impacts on wetlands would vary depending on the type of vegetation that is affected. For instance, temporary impacts on emergent wetlands are generally short-lived, with functions typically returning to pre-impact performance within one growing season. In contrast, temporary impacts on woody vegetation generally last longer because trees and/or shrubs may require several years or decades to achieve the size and stature necessary to provide pre-construction functions such as canopy habitat.

The following sections outline the range of potential temporary construction impacts that could occur under each alternative. Actual impacts would depend on the final configuration and design of the Preferred Alternative, construction footprint and methods, BMPs implemented during construction (see Section 5.1.1, Avoidance and Minimization During Design Development, and Section 5.1.2, Construction Best Management Practices), and performance of post-construction restoration. Direct construction impacts would be identified and quantified during the final design and permitting of the Preferred Alternative.

4.3.3.1 Preferred Alternative

Overall, temporary (construction-related) impacts on wetlands under the Preferred Alternative would be greater than under the South 344th Street Alternative, primarily because this alternative would affect Wetland WFW-02 while the South 344th Street Alternative would not (Table G3.4-7, Table G3.4-11).

Table G3.4-11 Potential Temporary (Construction-Related) Impacts of the Preferred Alternative on Wetlands

Wetland ID	Wetland Rating[1]	OMF Site Impacts	Mainline Impacts[2]
WFW-02	II	2.7	0
WFW-04	III	0.3	<0.05
WFW-07[3]	III	0	<0.05
WFW-10 Unit A	III	0	<0.05
WFW-14	IV	<0.05	0
WFW-15	III	<0.05	0.1

Table G3.4-11 Potential Temporary (Construction-Related) Impacts of the Preferred Alternative on Wetlands (continued)

Wetland ID	Wetland Rating[1]	OMF Site Impacts	Mainline Impacts[2]
WFW-32[4]	IV	0	<0.05
WFW-33	II	<0.05	0
Total Impacts		**3.0**	**0.1**

Notes:

(1) Wetland ratings (Hruby 2014) are preliminary and subject to review by permitting authorities. See Table G3.3-8 for information about the size and rating of individual wetlands.

(2) Impacts for the mainline design options would differ slightly (notes #3 and #4 below). See text for details.

(3) Wetland WFW-07 would only be impacted by the 55 mph Design Option.

(4) Wetland WFW-32 would be impacted by both mainline design options, but impacts would be slightly greater for the 55 mph Design Option.

Almost all direct temporary impacts to wetlands would result from site construction at Wetland WFW-02 for the 18th Place S road extension. Direct temporary wetland impacts due to mainline track construction would be minimal in comparison. The difference between the impacts of the design options for the curve at the northern end of the mainline track would be similar to those described for long-term impacts: a small portion (less than 0.05 acre) of Wetland WFW-07 would be intersected by the 55 mph Design Option; the 40 mph Alignment would avoid temporary impacts on that wetland and its buffer altogether (Tables G3.4-10 and G3.4-11).

4.3.3.2 South 344th Street Alternative

The extent of temporary, construction-related impacts on wetlands under the South 344th Street Alternative would be substantially less than under the Preferred Alternative, primarily because this alternative would not impact Wetland WFW-02, and it would not have any temporary impacts on Wetland WFW-04. However, this alternative would have more temporary impacts on wetland buffers than the Preferred Alternative would (Table G3.4-10). Site construction would have no temporary impacts on wetlands or wetland buffers; all temporary impacts would be associated with mainline track construction (Table G3.4-12).

Table G3.4-12 Potential Temporary (Construction-Related) Impacts of the South 344th Street Alternative on Wetlands

Wetland ID	Wetland Rating[1]	OMF Site Impacts	Mainline Impacts[2]
WFW-07[3]	III	0	<0.05
WFW-10 Unit A	III	0	<0.05
WFW-15	III	0	0.3
WFW-32[4]	IV	0	<0.05
Total Impacts		**0**	**0.4**

Notes:

(1) Wetland ratings (Hruby 2014) are preliminary and subject to review by permitting authorities. See Appendix G3, Ecosystem Resources Technical Report, for information about the size and rating of individual wetlands.

(2) Impacts for the mainline design options would differ slightly (notes #3 and #4 below). See text for details.

(3) Wetland WFW-07 would only be impacted by the 55 mph Design Option.

(4) Wetland WFW-32 would be impacted by both mainline design options, but impacts would be slightly greater for the 55 mph Design Option.

As with the Preferred Alternative, the 40 mph Alignment at its northern end also avoids the buffer of Wetland WFW-07 and would have fewer construction-related impacts than 55 mph Design Option. At its southern end, both tail track options would not temporarily impact wetlands, but buffers of Wetland WFW-05 would receive some temporary impacts (Table G3.4-10). The temporary wetland buffer impacts of the 40 mph Alignment paired with either tail track alignment, I-5 or Enchanted Parkway Tail Tracks, would differ by 0.1 acre (see Table G3.4-10 and Figures G3.4-4 and G3.4-5). The temporary wetland buffer impacts of the 55 mph Design Option paired with either tail track alignment are identical. Overall, temporary construction impacts on wetland buffers are lower under the 40 mph Alignment, regardless of tail track alignment.

4.3.3.3 Midway Landfill Alternative

The Midway Landfill Alternative would have no temporary, construction-related impacts on wetlands because there are no regulated wetlands or wetland buffers within the temporary impact footprint of this alternative.

4.4 Indirect Impacts

Indirect impacts include those effects that are related to the project but not part of it, and that may occur separated by distance or time. Other sources of indirect effects may be related to changes in the pattern of land use, population density, or water quality in the areas affected by the project. Indirect impacts may also occur through the implementation of mitigation measures for other environmental impacts, or through supporting projects that are not yet defined or considered part of the project alternatives.

For aquatic species and habitat, indirect impacts would be minimal because the surrounding areas are already heavily developed. OMF South is not expected to interfere with future projects that may provide habitat improvements, such as road projects that may improve fish passage or projects that may enhance vegetated and wetland areas in the project corridor. OMF South would be designed to ensure that it would not preclude future culvert replacement(s) by WSDOT to provide fish passage. Facilities that provide water quality treatment could minimize long-term indirect impacts on water quality in streams that provide habitat for fish sensitive to the toxic effects of contaminants in stormwater runoff. However, as discussed in the analysis of long-term impacts, treated water discharged from such facilities and untreated water that bypasses those facilities during major storm events may contain contaminants that can harm fish and other aquatic life.

Long-term indirect impacts on vegetation, wildlife, and wildlife habitat could include habitat loss or increased disturbance due to changes in land use patterns near the OMF South site. Such impacts would be unlikely under any of the project alternatives, however, because all three site alternatives are located in highly developed commercial, institutional, and/or industrial areas.

Indirect impacts from OMF South may result in long-term wetland degradation from stormwater discharges and alterations in wetland hydrology. Impacts to wetland hydrology would be minimized through the use of stormwater management facilities that meet the standards established by local, state, and federal agencies with regulatory authority. Facilities that provide water quality treatment could minimize long-term indirect impacts on water quality in wetlands. However, as discussed in the analysis of long-term impacts, treated water discharged from such facilities and untreated water that bypasses those facilities during major storm events may contain contaminants that can harm fish and other aquatic life.

4.5 Cumulative Impacts

Past actions have greatly changed the ecological landscape in the study area and vicinity, and ongoing and reasonably foreseeable future actions could contribute to additional cumulative impacts. To address the effects of past development, restoration programs and projects (e.g., aquatic and terrestrial habitat improvement projects, culvert replacement projects to eliminate barriers to fish passage barriers) are being planned and implemented throughout the region. The potential for any of the project alternatives to result in adverse cumulative impacts would be related to the direct impacts of that alternative. In other words, a project alternative with a greater extent and/or intensity of adverse impacts on ecosystem resources would have a greater risk of adverse cumulative impacts.

Permitted impacts for FWLE are 1.25 acres of wetland, 4.9 acres of wetland buffer, and 0.24 acre of riparian forest buffer (Sound Transit 2023). In addition, the Final EIS for FWLE identified impacts on 35 acres of forested habitat (Sound Transit 2016a). That EIS also analyzed impacts associated with the relocation of approximately 1,000 linear feet of stream channel (Bingaman Creek, which will be rerouted to meander around the columns supporting the elevated mainline tracks). These impacts have been mitigated through permitting process with regulatory agencies and local jurisdictions. The Federal Transit Administration (FTA) determined that FWLE will not impact fish passage in Bingaman Creek or elsewhere (FTA 2017); the project was designed to allow WSDOT to implement fish passage improvements on Bingaman Creek in the future, if necessary. In addition, by complying with WSDOT’s and local jurisdictions’ rules concerning tree replacement and the maintenance of visual quality, FWLE is expected to increase the amount of vegetated area over the long term.

Other reasonably foreseeable future projects that could adversely affect ecosystem resources in the study area include TDLE, Federal Way’s City Center Access project, Creekside Commons Townhomes development WSDOT’s SR 509 Completion project, and WSDOT’s I-5/SR 161/SR 18 Triangle project (this project was suspended in 2023, with no date set for resumption). All these projects are largely on developed or partially developed parcels. Nevertheless, possible short-term and long-term impacts of these projects include loss or degradation of vegetation, wildlife habitat, streams, wetlands, and associated buffer areas. Impacts of TDLE would contribute to those of the Preferred Alternative or the South 344th Street Alternative. Similarly, impacts of the Federal Way City Center Access project would contribute to those associated with construction of the mainline tracks north of the of the Preferred Alternative or the South 344th Street Alternative. The SR 509 Completion project area extends along I-5 as far south as the Midway Landfill Alternative, but the only proposed project element near the Midway Landfill site is an auxiliary lane on southbound I-5. Construction of an auxiliary lane would be unlikely to adversely affect ecosystem resources at or near the Midway Landfill Alternative.

Coupled with the impacts of the past, present, and future projects described above, the impacts of the project alternatives could contribute cumulatively to reductions in the area and function of ecosystem resources in the study area. The potential for future projects to adversely affect ecosystem resources in the study area would be limited, however, by regulatory review and/or permitting processes under federal, state, and local regulations. These reviews and permitting processes require the implementation of measures to avoid or minimize impacts on ecosystem resources, as well as compensatory mitigation for unavoidable impacts on wetlands, streams, and their buffers.

5 MITIGATION MEASURES

Sound Transit's policy on ecosystem mitigation is to avoid impacts on environmentally sensitive resources and provide adequate mitigation to ensure no net loss of ecosystem function and acreage as a result of agency projects (Sound Transit 2007). The proposed project would mitigate impacts on ecosystem resources in accordance with the mitigation sequencing requirements established by SEPA, the Clean Water Act (CWA), and local critical areas ordinances. In this context, mitigation sequencing is defined as first avoiding, second minimizing, then rectifying, reducing, compensating, and monitoring environmental impacts (WAC 197-11-768). As described below, the project alternatives would first avoid or minimize potential impacts on ecosystems resources to the greatest degree possible, and Sound Transit is committed to providing compensatory mitigation when avoidance is not practicable.

Proposed mitigation measures would include specific goals and objectives and specify monitoring criteria. The measures would consider compensatory opportunities for advance mitigation, mitigation banks, and in-lieu fee programs. Proposed compensatory mitigation measures and location(s) would be developed so that reviewing agencies can confirm the likelihood of meeting all stated objectives. These measures would be finalized during permitting.

5.1 Avoidance and Minimization

The project alternatives incorporate the avoidance and minimization of impacts as a guiding principle during preliminary and final design. The build alternatives for the proposed project would avoid or minimize potential impacts on ecosystems resources whenever practicable. Sound Transit would comply with standard specifications, BMPs, and applicable federal, state, and local mitigation requirements during design, construction, and post-construction activities. Sound Transit would meet all regulatory requirements and continue to implement proactive avoidance and minimization measures related to these BMPs in adherence with federal, state, and local regulations.

These strategies, along with others designed to avoid or minimize effects on other resources, would be implemented to effectively minimize the potential impacts on sensitive ecosystem resources. Examples of additional strategies include minimizing vegetation clearing, restoring temporarily affected areas, and preparing and implementing a revegetation plan.

5.1.1 Avoidance and Minimization During Design Development

The development of the design for OMF South was strongly influenced by the presence and location of wetlands, habitat features, vegetation conditions, and potential presence of fish and wildlife. The design was intended to minimize impacts on ecosystem resources and was reconfigured in several areas to further reduce impacts on important environmental features. For example, the design of the Preferred Alternative anticipates the use of elevated structures for tracks near sensitive resources (e.g., streams, wetlands). Compared to at-grade tracks, elevated structures require less ground disturbance and permanent fill, reducing long-term impacts to ecosystem resources.

Most of the project has been located within heavily developed areas and/or along major road corridors (i.e., I-5, SR 99), thereby avoiding impacts on large patches of undisturbed habitat. To minimize impacts on remnant habitat patches, the project abuts these major roads with the minimum margin allowed under transportation safety and planning requirements.

Sound Transit has committed to minimizing the need to place existing streams in new culverts and has designed the OMF South alternatives to avoid new stream piping whenever possible. However, as discussed in Section 4.1.2, under the Preferred Alternative, frontage improvements along S 336th Street to meet city standards would necessitate the replacement culverts that convey West Fork Hylebos Tributary under that roadway. The replacement structure would be designed and installed in accordance with WDFW’s Water Crossing Design Guidelines (Barnard et al. 2013), avoiding the potential for creation of barriers to fish passage. The existing culverts are identified as a partial barrier to fish passage.

Based on the interim design, the proposed replacement structure at this crossing would have a substantially larger hydraulic opening than the two pipes that currently convey the stream under the roadway. As such, the replacement structure would help restore the hydrological capacity at that crossing site, allowing sediment and organic debris to pass through and providing fish unhindered passage beneath the roadway. These benefits would be offset slightly by a reduction in the length of surface-flowing stream channel at this site: the replacement structure would be 3 feet longer than the existing, 86-foot-long pipes.

Another existing crossing structure would be replaced near the WSDOT stormwater facility north of S 344th Street. Under the Preferred Alternative, East Fork Hylebos Tributary would be conveyed under the 21st Avenue S extension and S 344th Street in a new structure that would replace the existing, approximately 315-foot-long culvert. Under the South 344th Street Alternative, this culvert would be replaced with an approximately equal length of surface-flowing stream. Requirements to maintain emergency vehicle access might necessitate placing 60 feet of the daylighted channel in a new crossing structure, reducing the length of restored channel.

The project design for the Preferred Alternative was adjusted to avoid and minimize impacts on streams, riparian areas, wetlands, and forested areas, particularly along East Fork Hylebos Tributary. For example, the proposed design of the Preferred Alternative includes a retaining wall along the eastern boundary of the OMF South site and along the northwestern boundary of the site to minimize impacts on streams and associated wetlands in those areas. In addition, the site of the OMF facility under the Preferred Alternative was shifted west to widen the corridor available for stream restoration.

In addition, Sound Transit placed priority on minimizing impacts on West Fork Hylebos Tributary and Wetland WFW-02 in the northwestern corner of the Preferred Alternative OMF South site. The design team determined that it would not be possible to completely avoid impacts in that area without compromising operations at the OMF South site. Working with that constraint, the design team developed a site layout that would affect a smaller area of the wetland. Sound Transit is actively exploring options for further reductions of the project footprint in that area.

Relocation and realignment could include constructing a new stream channel along approximately the same alignment as the existing channel, or it could entail moving the channel to a new alignment several dozen feet from the existing channel. Relocated stream segments would include meanders and other features that enhance the availability and diversity of aquatic habitats. Finally, in some cases, restored, daylighted channels would be constructed for stream segments currently contained within culverts. Daylighting would allow increased interaction between the stream and associated riparian vegetation, resulting in beneficial effects associated with restoring natural processes, such as organic input and flow attenuation.

Vegetation clearing and related habitat impacts were avoided and minimized to the degree feasible by focusing design elements, particularly staging and lay-down areas, in locations that are already developed or heavily disturbed. Sound Transit would restrict clearing activities to outside the active bird nesting period, to the extent possible, to comply with the Migratory Bird

Treaty Act administered by USFWS. If avoidance scheduling is infeasible, Sound Transit would conduct pre-construction surveys to determine the presence or absence of nesting migratory birds to assist in complying with the Migratory Bird Treaty Act.

5.1.2 Construction Best Management Practices

Sound Transit has developed BMPs to avoid and minimize impacts during construction. Many of these BMPs are based on the conditions likely to be set forth in project permits. The following subsections identify BMPs that would be implemented for sensitive areas in general, as well as BMPs specifically targeting fish and aquatic habitats, including water quality.

5.1.2.1 General BMPs for All Sensitive Areas

Sound Transit or the construction contractor would delineate construction limits with fencing and signage to prevent non-permitted impacts on ecosystem resources such as wetlands, riparian vegetation, or sensitive upland habitats. The intent of the fencing and signage would be to prevent impacts on sensitive sites outside the construction limits. The construction limits would be clearly marked with high-visibility construction fencing or some other method of demarcation before clearing or ground-disturbing activities begin. Clearing and ground-disturbing activities outside the construction limits would not be allowed. Temporarily cleared vegetation would be restored after construction is complete. Site restoration would include replanting disturbed areas with appropriate native vegetation, as soon as practicable.

Sound Transit would also implement appropriate measures to minimize the risk of introduction and spread of noxious and invasive plant and animal species. To minimize the risk of harm to species protected under the Migratory Bird Treaty Act, Sound Transit would consult with staff from WDFW or USFWS about measures to conserve migratory birds and their nests.

Sound Transit or its construction contractor would develop a Temporary Erosion and Sediment Control (TESC) plan that would be implemented during construction. The TESC plan would identify measures for preventing sediment from soil or rock stockpiles, excavated materials, or excess soil materials being conveyed by high water or storm runoff into sensitive habitats, including stream channels, wetlands, and riparian areas outside the construction limits. The contractor would implement the plan before discharging or allowing runoff from the site. Monitoring requirements specified in the TESC would provide feedback to make sure that the erosion control practices are operating properly and effectively. In addition, BMPs would be implemented to limit soil compaction in sensitive areas.

5.1.2.2 Fish and Aquatic Habitat Protection

Construction activities within or below the OHWL of waterbodies in the study area would comply with the terms and conditions set forth in the HPA and other permits (such as the CWA Section 401 water quality certification) issued for the project, including provisions designed to avoid or minimize the potential for adverse effects on habitat in receiving waters. Such provisions may include restrictions on construction below the OHWL to minimize the risk of adverse effects on downstream fish during highly sensitive life history stages (e.g., spawning, rearing).

In accordance with typical requirements of an HPA, if LWD must be moved to allow the reasonable use of an over-water or in-water facility, the LWD would be relocated downstream, where it would continue to provide aquatic habitat function.

Any culverts installed in waters of the state would comply with the fish passage requirements specified in WAC 220-110-070 and would be designed using the stream simulation methodology outlined in WDFW's Water Crossing Design Guidelines (Barnard et al. 2013). Any affected streambeds or stream banks adjacent to culverts would be permanently restored with plantings of native or approved woody and herbaceous species within one year of completion of each phase of construction. Bank protection, if required, would follow the guidelines set forth in Washington State's Integrated Streambank Protection Guidelines (Cramer et al. 2003).

Water quality protection would be addressed through compliance with the CWA Section 401 water quality certification and the National Pollutant Discharge Elimination System (NPDES) construction stormwater general permit issued for the project. The goal of the permit is to reduce or eliminate stormwater pollution and other impacts on surface waters from construction sites. The project would also be required to develop a Stormwater Pollution Prevention Plan (SWPPP) that implements BMPs for identifying, reducing, eliminating, or preventing sediment and erosion problems on site. The SWPPP would include a TESC plan; spill prevention, control, and countermeasures plan; concrete containment and disposal plan; dewatering plan; and a fugitive dust plan.

Specific BMPs for avoiding or minimizing potential impacts on water quality include the following:

- Operating heavy equipment above the OHWL, except as specifically authorized under the HPA issued for the project.
- Covering temporarily stored materials with plastic or other impervious material during rain events to prevent sediments from being washed from the storage area to surface waters.
- Inspecting all temporary and permanent erosion and sedimentation control measures on a regular basis and maintaining and repairing them as needed to ensure continued performance of their intended function.
- Preventing the discharge of turbid water to streams and wetlands. Turbid wastewater may be routed to temporary or permanent detention facilities or to upland areas that provide adequate infiltration.
- Cleaning and inspecting all equipment to be used for construction activities before it arrives at the project site to ensure no potentially hazardous materials are exposed, no leaks are present, and the equipment is functioning properly. Should a leak be detected on heavy equipment used for the project, the equipment would be repaired before use. Construction equipment and vehicles would be maintained to prevent them from leaking fuel or lubricants.
- Preventing contact of uncured concrete and/or concrete byproducts with streams or water conveyed directly to streams during construction, in accordance with WAC 220-110-270(3). A concrete truck chute cleanout area or equally effective BMP would be established to properly contain wet concrete.

5.1.3 Design and Operation Best Management Practices

The project would install permanent stormwater runoff treatment and flow control facilities where needed according to the requirements of applicable stormwater and surface water design manuals. Where applicable and feasible, the project would incorporate stormwater conveyance and management facilities that promote infiltration. Sound Transit would design and construct permanent stormwater treatment facilities and flow-control measures to minimize impacts on stream water quality and flow.

The project would select, design, and install runoff treatment BMPs that are best suited to the site conditions and best capable of achieving the required levels of treatment (subject to negotiation with the local jurisdiction and/or Ecology). The project would not reroute existing drainage configurations to the extent that stormwater from one basin or subbasin is conveyed and discharged to another.

The project would implement integrated pest management techniques, in accordance with current Ecology water quality agreements, to minimize the impact on aquatic and terrestrial environments.

5.2 Rectifying and Reducing Impacts over Time

To the extent that impacts cannot be avoided or minimized through BMPs, Sound Transit would implement restoration measures to rectify temporary impacts and reduce their effects over time. Immediately following project construction, Sound Transit would begin restoring temporarily disturbed wetlands, streams, and buffer areas. The length of time that would be required for site restoration to effectively replace habitat functions would vary. To the extent feasible, temporarily disturbed wetlands, streams, and their buffers would be restored to preconstruction conditions, or better, and planted with appropriate native species when construction activities are finished. Sound Transit would conduct detailed site surveys to reestablish topography. Restoration would include soil amendment where needed and vegetation replacement. Upland forested vegetation disturbed within construction staging areas would be revegetated with native species generally within 1 year following construction. Invasive, nonnative vegetation would be removed permanently from temporarily affected areas to improve the overall habitat for wildlife. Ecological functions in other temporarily disturbed areas may not be restored for many years; these long-term temporary impacts would require compensatory mitigation.

Under the Preferred Alternative or the South 344th Street Alternative, construction of the OMF and associated elevated mainline and test tracks would necessitate the realignment of the stream channel for East Fork Hylebos Tributary. The new channel would be designed to maintain flows and water quality conditions. To the extent practicable within site constraints, the stream channel in this area would be reconfigured to include meanders and other in-stream features that enhance the availability and diversity of aquatic habitats. However, opportunities for rectification would be limited by the presence of the OMF site to the west and the mainline tracks to the east. In addition, the presence of support columns near the stream would constrain options for channel configuration.

5.3 Compensatory Mitigation

Sound Transit has committed to achieving no net loss of wetland function and area on a project-wide basis. For unavoidable long-term impacts on wetlands, streams, and their buffers, Sound Transit would develop a compensatory mitigation plan during the permitting phase in accordance with applicable federal, state, and local requirements and guidelines. These guidelines and regulatory standards include the Federal Compensatory Mitigation Rule (40 Code of Federal Regulations [CFR] § 230 and 33 CFR § 325 and 332); interagency guidance (Ecology et al. 2021 or as updated); and the applicable local critical areas ordinances. To achieve no net loss of wetland function and area, Sound Transit could use a combination of mitigation strategies, such as off-site compensatory mitigation within the Hylebos Creek watershed, mitigation bank, and/or in-lieu fee program. Where the project affects any fish-bearing streams or fish passage structures, Sound Transit would coordinate with the appropriate Tribes and agencies (e.g., WSDOT, WDFW) on mitigation concepts, restoration priorities and methods.

Compensatory mitigation would be provided for construction impacts lasting more than one growing season, and for permanent conversion of wetlands from one vegetation type to another (e.g., forested wetland to emergent or scrub-shrub wetland), as well as for indirect impacts on wetlands. Generally, compensation for long-term temporary impacts is one-quarter of the typical ratio for long-term permanent impacts and one-half for conversion of wetlands. Impacts to wetland buffers would generally be replaced at a minimum ratio of 1:1, using buffer enhancement. In areas where stream buffers and wetland buffers overlap, mitigation for impacts would be based on the local jurisdiction’s requirements for mitigating impacts either to wetland buffers or to stream buffers – whichever requirements are more stringent.

The 2008 Federal Compensatory Mitigation Rule established a preference for the use of approved wetland mitigation banks and in-lieu fee programs over the development of permittee-responsible mitigation sites (40 CFR § 230.93 and 33 CFR § 325 and 332). The study area is located within the service areas of one mitigation bank (the Port of Tacoma’s Upper Clear Creek mitigation bank, certified in June 2020) and one in-lieu fee program (the King County Mitigation Reserves Program).

Sound Transit would also comply with local ordinances regarding tree replacement ratios. Tree removal within the I-5 corridor would be mitigated according to the WSDOT Roadside Policy Manual.

To satisfy federal and state permitting authorities, Sound Transit plans to follow the federal mitigation hierarchy (Corps and EPA 2008), which prioritizes approved mitigation banks and in-lieu fee programs, where available. However, the city of Federal Way and the Puyallup Tribe of Indians prefer use of in-kind wetland mitigation within the same watershed.

5.3.1 Approved Mitigation Bank

The Port of Tacoma’s Upper Clear Creek mitigation bank was certified in June 2020 and could be available for use to offset project impacts in the Hylebos Creek watershed if credits are available at the time of permitting. The city of Federal Way’s updated critical areas ordinance allows for compensatory mitigation to be provided through a certified mitigation bank as an alternative method for mitigation. However, use of the bank must be approved by the city under its discretionary authority.

5.3.2 County In-Lieu Fee Programs (Mitigation Reserves Program)

King County has developed an in-lieu fee program to mitigate for wetland impacts. The King County In-Lieu Fee Program is called the Mitigation Reserves Program, which was approved by the Corps in March 2012 (King County 2011). The program includes service areas within the watersheds affected by OMF South (i.e., Green River and Central Puget Sound) that are in King County. The city of Federal Way’s updated critical areas ordinance allows for compensatory mitigation to be provided through a certified in-lieu fee program, if approved by the local jurisdiction.

5.3.3 Project-Specific Mitigation Developed by Sound Transit

Sound Transit will likely be required to mitigate for some portion of unavoidable impacts on wetlands through permittee-responsible, project-specific mitigation. Project-specific mitigation, if required, will be developed in accordance with the federal Final Compensatory Mitigation Rule (40 CFR Part 230) and joint guidance developed by Ecology, the Corps, and the EPA (Ecology et al. 2021 or as updated). This guidance supports the implementation of a watershed approach to selecting mitigation sites. This approach allows for a greater degree of flexibility in selecting mitigation sites and potentially greater value created for the watershed than use of on-site mitigation. Preliminary off-site mitigation areas have been identified during an initial screening process and are included in Attachment G3-8 of this report. These or other sites may be used for off-site wetland mitigation, which may involve city-owned parcels or require property acquisition in the Hylebos watershed. Sound Transit anticipates using this approach to determine the appropriate location, amount, and types of compensatory mitigation to compensate for the specific type and degree of functions affected by the project.

In cooperation with resource agencies and Tribes, Sound Transit would develop plans to mitigate the effects of the project on wetlands, streams, and regulatory buffers on a watershed basis. To the extent possible, off-site compensatory mitigation sites would be identified and would compensate for lost values in-kind. It may be necessary to use several sites and mitigation approaches given the project size, the variety of impacts, complexity of identifying mitigation opportunities, and mitigation requirements.

The project would adhere to the mitigation requirements (such as mitigation ratios) specified by federal regulators, Tribes, state resource agencies, and the city of Federal Way. Impacts on streams would be mitigated through restoration actions on site and developed in collaboration with federal, state, and local regulators, and Tribal biologists.

Wetland Delineation Methodology

Federal Transit Administration

SOUNDTRANSIT

1. WETLAND IDENTIFICATION AND DELINEATION

Parametrix biologists used the methods specified in the U.S. Army Corps of Engineers Wetland Delineation Manual (Environmental Laboratory 1987) and the indicators described in the Regional Supplement to the Corps of Engineers Wetland Delineation Manual: Western Mountains, Valleys, and Coast Region (U.S. Army Corps of Engineers [Corps] 2010) to delineate on-site wetlands.

Wetlands are defined as those areas that are inundated or saturated by surface water or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions. An area must meet these three criteria or exhibit at least one positive field indicator of wetland vegetation, soils, and hydrology to be considered a wetland. Wetland determination data forms from the Regional Supplement to the Corps of Engineers Wetland Delineation Manual: Western Mountains, Valleys, and Coast Region (Corps 2010) were recorded for each wetland.

1.1 Vegetation

During the field investigations, the biologists observed the dominant plant species and recorded each on data forms for each sample plot. They evaluated dominant plants and their wetland indicator status to determine whether the vegetation was hydrophytic. Hydrophytic vegetation is generally defined as vegetation adapted to prolonged saturated soil conditions. To meet the hydrophytic vegetation criterion, more than 50 percent of the dominant plants must be Facultative, Facultative Wetland, or Obligate, based on the plant indicator status category assigned to each plant species by the Corps (Lichvar et al. 2016).

Scientific and common plant names follow currently accepted nomenclature. Most names are consistent with Flora of the Pacific Northwest (Hitchcock and Cronquist, 2nd Edition 2018), Plants of the Pacific Northwest Coast (Pojar and MacKinnon 2004), and the U.S. Department of Agriculture (USDA) PLANTS Database (USDA 2020). However, scientific names listed in the 2016 National Wetland Plant List (Lichvar et al. 2016) were used as the final authority in preparing determination forms and determining species indicator status.

1.2 Soils

Generally, an area must have hydric soils to be a wetland. Hydric soil forms when soils are saturated, flooded, or ponded long enough during the growing season to develop anaerobic conditions in the upper layers. Biological activities in saturated soil result in reduced oxygen concentrations that create a preponderance of organisms using anaerobic processes for metabolism. Over time, anaerobic biological processes produce certain color patterns in mineral soils and/or enhance accumulation of organic soils (e.g., peat), which are used as field indicators of hydric soil. Typically, low-chroma colors are formed in the soil matrix. Bright-colored redoximorphic features form within the matrix under a fluctuating water table. Other important hydric soil indicators include organic matter accumulations in the surface horizon, reduced sulfur odors, and organic matter staining in the subsurface. Soils were examined by excavating sample plots to a depth of 16 inches or more, wherever feasible, to observe soil profiles, colors, and textures. Munsell® color charts (Munsell® Color 2015) were used to describe soil colors and the Field Book for Describing and Sampling Soils (Schoenebergerm et al. 2012) was used to describe the soil texture class.

1.3 Hydrology

The study area was examined for evidence of hydrology. An area is considered to have wetland hydrology when soils are ponded or saturated consecutively for 12.5 percent of the growing season (Environmental Laboratory 1987). The growing season generally occurs from late February (February 27) to late November (November 21) (based on SeaTac Airport weather station climate data). Therefore, ponding or saturation must be present for approximately 33 consecutive days within the growing season. Wetland hydrology is determined by the identification of specific indicators described in the regional supplement (Corps 2010). The observation of one primary indicator or two secondary indicators is a positive indication of wetland hydrology. The project is located in Major Land Use Area 2, within Land Resource Region A (Corps 2010; NRCS 2006). Within these regions, primary and secondary indicators of hydrology are described by group and comprise:

- Group A (Observation of Surface Water or Saturated Soils): Surface inundation, high water table, and saturated soils
- Group B (Evidence of Recent Saturation): Water marks, sediment and drift deposits, algal mats, iron deposits, surface soil cracks, inundation visible on aerial imagery, sparsely vegetated concave surfaces, salt crusts, and aquatic invertebrates. *Secondary*: Water-stained leaves and drainage patterns
- Group C (Evidence of Current or Recent Soil Saturation): Hydrogen sulfide odor, oxidized rhizospheres along living roots, presence of reduced iron, and recent iron reduction in tilled soils. *Secondary*: Dry-season water table and saturation evident on aerial imagery.
- Group D (Evidence from Other Site Conditions or Data): Stunted or stressed plants. *Secondary*: geomorphic position, shallow aquitard, vegetation Facultative-neutral test, raised ant mounds, and frost-heave hummocks

SOUND TRANSIT STREAM HABITAT ASSESSMENT GUIDELINES

1. Introduction

Sound Transit projects often intersect with and affect streams. To comply with local, state, and federal rules and regulations, Sound Transit assesses stream conditions, determines stream impacts that will occur as a result of a project, and mitigates those impacts as appropriate. The analytical methodologies used and level of detail needed to meet these requirements depends on a variety of factors including: 1) the stage of project development and complexity of the project, 2) the extent to which Sound Transit has property access to streams, and 3) the magnitude of impact. Less detailed information is typically collected during planning and early design stages such as during SEPA/NEPA environmental review and preliminary engineering because rights-of-entry are not granted onto privately owned properties, thus restricting access to streams. Also, at this stage, multiple alternative alignments may be under consideration, making more labor-intensive field investigations less feasible from the standpoint of cost and time. At later stages of project development, once the project to be built is selected or final design is underway, more detailed analyses may be appropriate depending on access, the magnitude of potential impacts, and the types of environmental permits that may be necessary to construct the project.

Various methodologies exist on how to approach stream assessments in Washington and no one methodology is required, or is applicable to all projects or to all stages of project development. In addition, Native American tribes with fishing rights often request specific information about the effects of a project on both existing fish use and potential fish use of a stream. In this context, Sound Transit seeks to achieve greater consistency in how it approaches the assessment of streams at various stages of project development and under various conditions. The purpose of this document is to establish general guidelines for applying various stream assessment methods to Sound Transit projects based on the most commonly used methodologies in Washington. The information presented herein is for guidance only and is based on some of the most common scenarios encountered on Sound Transit projects. Sound Transit recognizes that other scenarios are possible and that professional judgment will be necessary when considering the best approach for specific projects. Proper application of professional judgment may reduce the collection of extraneous information, and reduce project effort and expense. The intent of these guidelines is to provide some level of consistency in Sound Transit's approach to assessing streams so that local, state, and federal regulators generally know what to expect during project reviews.

For the purposes of this document, project development is categorized into two phases: the initial environmental review and preliminary engineering phase (Phase 1) and the permitting/final design phase (Phase 2). These are further described below:

- **Phase 1 Projects** – Planning stage that includes environmental review under SEPA/NEPA and conceptual and preliminary design. At this stage, various alignments or sites may initially be under consideration, and Sound Transit may or may not have rights-of-entry to the properties being evaluated. In general, objectives at this stage of project development are to:

1) Identify streams within the study area
2) Characterize in-stream and riparian conditions (including fish use and barriers to fish use of the stream) based on readily available information and visual observations as possible
3) Determine potential impacts to streams for the alternative(s) under consideration during the environmental review process, and
4) Identify conceptual-level mitigation opportunities for impacts to streams (aquatic and riparian habitats).

Phase 1 projects may include Endangered Species Act consultation, with the overall objective of being able to make and support accurate effect determinations for federally listed aquatic species potentially occurring in affected streams. Phase 1 of Sound Transit's project development culminates with completion of the NEPA/SEPA environmental review process and Sound Transit's selection of a specific project alternative to build.

- **Phase 2 Projects** – Final project design stage that includes environmental permitting and detailed mitigation to address project-related impacts to streams. At this stage, full access is typically available for the project. The overall objective is to secure necessary environmental permits/approvals including but not limited to local critical areas permits, a Hydraulic Project Approval (HPA) from the Washington Department of Fish and Wildlife (WDFW), a Clean Water Act Section 404 permit from the United States Army Corps of Engineers (Corps), and a 401 Water Quality Certification or Coastal Zone Management Consistency Determination from the Washington State Department of Ecology (Ecology).

Section 2 of this guidance document, **Using the Stream Assessment Flowcharts**, helps guide the reader in determining the appropriate level of data collection during the two project phases described above. To do this, a flowchart has been created for Phase 1 and Phase 2 projects, taking into account various project variables. The flowcharts and overview of how to use them are provided in Section 2. The flowcharts in Section 2 are supported by additional tools and more detailed information on various methodologies described in **Section 3 - Data Collection for Key Aquatic Habitat Elements**. Both Section 2 and Section 3 are organized around five stream features, referred to as Key Aquatic Habitat Elements and described below.

General recommendations for the appropriate use of these guidelines, as well as a discussion of their limitations, are provided in **Section 4 - Considerations and Limitations**.

2. Using the Stream Assessment Flowcharts

The flowcharts should be used to determine the appropriate data needs and level of field assessment that will be required for a project. Working through the flowcharts with site specific information will require the collection of qualitative and/or quantitative information on various Key Aquatic Habitat Elements. These elements are the key habitats and stream features that may be impacted by a project and are directly related to ecological functions that support a stream ecosystem. The Key Aquatic Habitat Elements are:

- ***riparian vegetation,***
- ***physical in-stream habitat,***
- ***biological connectivity,***

- ***water quality and quantity, and***
- ***fish presence, fish habitat use, and stream typing***.

Information would be gathered during site visits or collected using specific survey techniques. The various "levels" of data collection for each Key Aquatic Habitat Element have been classified into one of three categories, or "Tracks". Tracks A, B, and C represent an increasing level of detail for data collection and generally correlate to the phase of the project, the extent to which access is available, and/or the magnitude of stream impact.

2.1 Phase I Projects

Figure 1 on page 4 is the stream assessment flowchart for planning-level projects. It shows the general process to follow when considering potential stream impacts associated with Phase 1 projects. For all Phase 1 projects that include stream habitats, regardless of access or impact level, the first step is to collect background information on each of the Key Aquatic Habitat Elements associated with each stream in the study area. To help guide these efforts, see **Section 3 – Data Collection for Key Aquatic Habitat Elements**. Section 3 includes more detailed information on specific data sources to consult when collecting this information. The information gathered will help form the basis of the *Existing Conditions* or *Affected Environment* section of the environmental document being prepared for the project.

After collecting background information, some level of data should also be collected in the field. The data collected and the stream assessment methods used will vary for Phase 1 projects depending on 1) whether or not impacts are anticipated impact, and 2) whether or not the project team has right-of-entry to parcels that contain streams.

If access is limited, Track A Methods should be used for each Key Aquatic Habitat Element to the extent feasible. Areas where access to streams is not limited include existing Sound Transit right-of-way, WSDOT right-of-way, or other publicly-owned rights-of-way such as parks. In these areas, the project team should consider the anticipated level of impact to each Key Aquatic Habitat Element. The level of analysis required for a given Key Aquatic Habitat Element should be commensurate with the potential for impacts at a given site. In order to appropriately size the analysis, the flowchart requires consideration of whether or not impacts are expected to occur within the stream environment, looking in turn at each of the Key Aquatic Habitat Elements. For Phase 1 projects, a simple determination of either "Impact" or "No Impact" should be made for each Key Aquatic Habitat Element as presented in Table 1 (see page 5). The results of this analysis will help determine the level of data collection and analysis appropriate for each ecological function. If impacts are anticipated, the project study team should coordinate with Sound Transit environmental staff before initiating Track B data collection efforts as the data may already have been gathered by others or a shift in the project footprint may occur that negates the need to do more detailed surveys.

Depending on the outcomes from using the stream assessment flowchart for Phase 1 projects, various levels of data collection (either Track A or Track B) will need to be conducted. For information on specific stream habitat assessment methods to use under Track A or Track B, refer to **Section 3 – Data Collection for Key Aquatic Habitat Elements.** Tables 3 and 4 in that section outline pertinent assessment methods for each Key Aquatic Habitat Element, including detailed information on specific analysis metrics and survey methods that may be appropriate under Tracks A and B.

Table 1 Impact Classification for Phase I Projects Based on Impacts to Key Aquatic Habitats

Key Aquatic Habitat Element	Impact Classification	
	No Impact	**Impact**
Riparian Vegetation	No clearing within riparian zone	Clearing riparian vegetation, OR Removing significant trees[1]
Physical In-Stream Habitat	No in-water work or disturbance to bed and streambank below OHWM[2]	Working in-water involving bank hardening, OR Installing fish habitat features (e.g., LWD[3] or boulders), OR Altering substrate
Biological Connectivity	No installation, removal, or alteration of culverts, bridges, weirs, or other potential passage barriers	Replacing or installing culverts, weirs, or bridges in non-fish bearing waters
Water Quality and Quantity	No new stormwater discharges or increases in impervious surface	Adding new stormwater discharges or increasing impervious surface
Fish Presence, Fish Habitat Use, and Stream Typing	No in-water or riparian impacts	In-water or riparian impacts occur

[1] Significant trees should be defined using the local jurisdiction's Critical Areas and/or Urban Forestry code sections. If significant trees are not defined by local code, assume significant trees are those trees 6-inches or greater dbh (diameter breast height).
[2] OHWM – ordinary high watermark
[3] LWD – large woody debris

2.2 Phase 2 Projects

Figure 2 on page 6 is the stream assessment flowchart for projects in final design. It shows the general process to follow when assessing streams in greater detail for Phase 2 projects that involve stream impacts. For Phase 2 projects, access to all riparian areas is assumed for purposes of conducting field work using either Track B or Track C methods. In the unusual event that access to all parcels is not available during Phase 2, Track A methods should be used to the extent feasible.

Using more detailed project design drawings, the level of data collection for Phase 2 projects will vary depending on the severity of impacts to Key Aquatic Habitat Elements. For each stream impact area, impacts should be classified as either a "Minor Impact" or "Substantial Impact". Table 2 on page 7 should be utilized to help classify potential Phase 2 project impacts on each Key Aquatic Habitat Element, based on specific project activities and quantification of expected impacts to each habitat element. However, it should be noted that the criteria may be adjusted based on the relative severity of project impacts within each project area. The project study team should coordinate with Sound Transit environmental staff to confirm the impact classification and intended data collection track before initiating data collection, as some or all of the data may already have been gathered by others, or a shift in alignment may occur that negates the need to do more detailed survey.

Figure 2
Stream Assessment Flowchart for Sound Transit Phase 2 Projects

Table 2 Impact Classification for Phase 2 Projects Based on Impacts to Key Aquatic Habitats

Key Aquatic Habitat Element	Impact Classification	
	Minor Impact	**Substantial Impact**
Riparian Vegetation	Clearing less than 5,000 square feet of riparian vegetation, OR Removing 1 to 5 significant trees[a]	Clearing riparian vegetation in amounts exceeding minor impacts[1]
Physical In-Stream Habitat	In-water work involving bank hardening of <20 linear feet, OR Installing fish habitat features (e.g., LWD[2] or boulders), OR Altering substrate < 100 square feet	In-water work exceeding thresholds for minor impacts, OR stream straightening (meander loss) OR Site will be used as a compensatory mitigation site
Biological Connectivity	Replacing or installing culverts or weirs in non-fish bearing waters	Replacing or installing culverts, fishways, or weirs in fish-bearing waters
Water Quality and Quantity	Adding new stormwater discharges or increasing impervious surface where all stormwater is treated and detained and no 303(d) listed or TMDL[3] reaches	Adding new stormwater discharges or increasing impervious surfaces where discharge to 303(d)/TMDL[3] reach occurs, OR where full treatment and detention does not occur
Fish Presence, Fish Habitat Use, and Stream Typing	Minor impacts to one or more key aquatic habitats listed above	Substantial impacts to physical habitat or riparian vegetation aquatic habitat elements, OR project involves any changes (negative or positive) in fish passage conditions, OR where stream diversions/fish removal activities occur

[1] Significant trees should be defined using the local jurisdiction's Critical Areas and/or Urban Forestry code sections. If significant trees are not defined by local code, assume significant trees are those trees 6-inches or greater dbh (diameter breast height).
[2] LWD – large woody debris
[3] TMDL – total maximum daily load

Depending on the outcomes from using the stream assessment flowchart for Phase2 projects, various levels of data collection (either Track B or Track C) will need to be conducted for each Key Aquatic Habitat Element as appropriate. For information on specific stream habitat assessment methods to use under Track B or Track C, refer to **Section 3 - Data Collection for Key Aquatic Habitat Elements.** Tables 3 and 4 in that section outline pertinent assessment methods for each Key Aquatic Habitat Element, including detailed information on specific analysis metrics and survey methods that may be appropriate under Tracks B and C.

3. Data Collection For Key Aquatic Habitat Elements

Once the user has taken their Phase 1 or Phase 2 project through the appropriate flowchart in Section 2, Section 3 should be consulted to obtain more detailed information on specific data sources and stream assessment methodologies. Table 3 summarizes the recommended data to be collected for streams during all stages of project development. This includes background information, which should be collected in all cases, as well as field data collection for Tracks A, B, and C, which will depend on the anticipated level of impact to each Key Aquatic Habitat Element. The information in Table 3 is organized by Key Aquatic Habitat Element. Collection and assessment techniques for each Key Aquatic Habitat Element are described in more detail below. These data needs and assessment procedures have been selected to be generally applicable over the wide range of project types and permitting scenarios encountered by Sound Transit. During project development, the recommendations provided below may need to be adjusted based on project-specific input from regulatory agencies and Tribal entities.

3.1 Riparian Vegetation

For detailed information on specific riparian habitat assessment techniques and methods, see the *Oregon Riparian Assessment Framework* (Clarke, 2004) or Winward (2000). A common method for estimating canopy coverage is presented in (Daubenmire, 1959).

3.1.1 Background Information

1) Review existing literature –Reports or data sources that may contain information for reach or sub-basin scale riparian conditions include:

- The Washington State Conservation Commission Limiting Factors Analysis, organized by Water Resource Inventory area (http://scc.wa.gov/directory/ or http://www.eopugetsound.org/articles/water-resource-inventory-areas-puget-sound)
- Information on rare plants distribution from the Washington Department of Natural Resources Natural Heritage Program Database at: http://www.dnr.wa.gov/ResearchScience/HowTo/ConservationRestoration/Pages/amp_nh_data_instructions.aspx
- Local watershed analysis or stream assessment reports
- Local Shoreline Master Program Inventory reports Shoreline Master Program Inventory reports http://www.ecy.wa.gov/programs/sea/shorelines/smp/citizen.html

2) Review aerial photographs and any available site photos.

- Google Earth – also view past riparian conditions using historic photos on site
- Bing Maps – Birds Eye View feature is useful for assessing riparian conditions
- Digital or hardcopy orthophotos

3) Based on the results of steps 1) and 2) above, summarize the following:

- General vegetation type (forested, shrub, herbaceous, none (bare earth/built)),
- Tree canopy type (deciduous, coniferous, or mixed)
- Approximate density of vegetation types (dense or sparse),
- Approximate width of buffer on each streambank at project site (based on aerial photos), and
- Estimated average riparian buffer width upstream and downstream of project site.

Table 3. Overview of Data Collection Needs For Key Aquatic Habitat Elements

Key Aquatic Habitat Element[1]	Background Information[2]	Track A[3] – Limited Site Access or No Impact	Track B – Site Access and Minor Impacts	Track C – Site Access and Substantial Impacts OR Site to be Used as Compensatory Mitigation
Riparian Vegetation	1) Review existing literature 2) Review aerial photographs and existing site photos 3) Characterization should include: - vegetation type (i.e., forested, shrub, herbaceous, built, coniferous, deciduous, genus and species if possible), - relative vegetation densities	1) Site visit with qualitative description of riparian conditions: - vegetation type, height, and relative density - width/length of riparian zone - presence of overhanging or fallen vegetation/stream cover - presence of invasive plant species (estimate percent cover if possible)	1) Collect qualitative and quantitative field data from riparian zone including: - approximate height for each vegetation layer - approximate tree/shrub densities - identify invasive species and observed snags/dead and down trees - width, length, and area of functioning riparian zone - stream banks vegetation type, height, and density - percent vegetation that covers the stream - qualitative evaluation of known limiting riparian factors such LWD[3] or shade limitations	Collect Track B data, supplemented by tree counts, GPS survey, or professional land survey within forested riparian impact area to include: - tree species - tree diameters - estimated tree heights - locations of snags/dead and down
Physical In-Stream Habitat	1) Review existing literature 2) Review aerial photographs, topographic maps and site photos 3) Characterization should include: - stream width - dominant in-stream sediment - LWD[4] presence - channel morphology - streambank condition	1) Site visit to qualitatively assess the following through visual observations: - stream width - LWD presence - general channel morphology - general bank condition - dominant stream substrate - relative amount of instream cover and refuge **ALSO SEE TABLE 4 FOR MORE DETAILS**	1) Site visit to quantitatively assess the following conditions within, upstream, and downstream of project site: - wetted and OHWM[5] stream width - LWD size, location, and type - channel morphology - pool, riffle, run, glide - bank condition - stability/armoring - stream substrate - dominant/subdominant and particle distribution **ALSO SEE TABLE 4 FOR MORE DETAILS**	Same as Track B, but specific habitat impacts or intended use for mitigation may require: 1) Track B data collection over a wider area 2) GPS/professional survey of habitat elements delineated in Track B, or 3) detailed quantitative analysis of habitat elements (e.g., bulk substrate analysis, micro-channel morphology) **ALSO SEE TABLE 4 FOR MORE DETAILS**
Biological Connectivity	1) Review existing literature on existing fish passage conditions/barriers and check the WDFW Fish Passage Barrier Map 2) If no barriers are recorded online, Track B/C methods may be required regardless of impact level 3) Review aerial photographs to identify potential barriers at site, upstream, or downstream 4) Review topographic maps and watershed analyses	1) Site visit to qualitatively assess the following information on man-made fish passage structures: - type/material of structure - approximate size/configuration of structure - condition of structure (i.e. wear, damage, etc.)	1) Site visit to quantitatively assess man-made structures: - relative inlet and outlet elevations - stream channel bankfull width 2) If necessary, conduct WDFW Level A Culvert analysis per WDFW (2009) to assess status as fish passage barrier. Check with WDFW prior to conducting the analysis; they may already have that information, particularly if the culvert is on WSDOT right-of-way	Same as Track B, but in some cases coordination with design team on conducting a WDFW Level B culvert analysis per WDFW (2009) may be necessary to accurately assess barrier status
Water Quality and Quantity	1) Review existing literature/databases for information on: - water quality/contaminants, - stream temperatures, - flow data - water quality/quantity limiting factors	1) Site visit with qualitative description of: - type/material of outfall/drainage structure - approximate size/configuration/condition of outfall/drainage structure - visual estimate of streamflow and stream velocity - stream temperature - presence of septic systems within the project area - Water source (stormwater, other?)	No additional effort	No additional effort
Fish Presence, Fish Habitat Use, and Stream Typing	1) Review existing literature/databases for information on: - fish presence and fish habitat use - stream typing - contributing basin area - natural/manmade barriers downstream	If result of background information does not provide complete or definitive results, conduct site visit and make preliminary determination based on WAC 222-16-031. Qualitatively assess the following: - stream width/OHWM, - flow conditions, - fish observations	If result of background information does not provide complete or definitive results proceed with one or more of the following options, as appropriate: 1) Request government/Tribal fish use/stream typing assistance 2) Utilize a qualified biologist to estimate fish presence/absence based on habitat conditions within, upstream, and downstream of site Conduct reconnaissance site visit to identify natural downstream barriers	Same as Track B, but in extraordinary circumstances, fish sampling by a qualified biologist may be appropriate[6]. Sampling techniques could potentially include: - snorkel surveys - minnow traps - electrofishing

[1] See text in Section 3 – Data Collection for Key Aquatic Habitat Elements for more specific information on each habitat element

[2] Background information should be compiled regardless of access situation or level of impacts

[3] If lack of access, the information for Track A should be collected in the field from adjacent publicly accessible properties or right of way to the extent possible/practical

[4] LWD – large woody debris

[5] OHWM – ordinary high water mark

[6] If information collected as part of Track A or Track B does not provide the required level of certainty on fish presence and stream typing, and no natural barrier exists downstream, generally assume fish presence and consult with ST environmental staff. These activities will require a Scientific Collection Permit from WDFW, and in accordance with WAC 220-20-045. Electrofishing, per requirements in WAC 220-20-045, should only be used to assess fish presence under extraordinary circumstances where such actions are pre-approved by ST (e.g., this information is tied to a permit condition or the information is crucial for design of a substantial design element such as road or culvert)

3.1.2 Track A Information

After collecting and synthesizing relevant background information on riparian vegetation conditions within the project area, conduct a reconnaissance-level site visit within existing Sound Transit or public right-of-way/easement areas. Provide qualitative description of riparian conditions including the following:

- Note buffer vegetation type – e.g., forested, shrub, herbaceous, none (bare earth/built). Identify shrub and/or tree species if possible, including any observed invasive species.
- Note relative buffer vegetation density (e.g., sparse, moderately dense, dense) and approximate height of each vegetation layer, particularly the tree layer
- Note observable width/length of riparian zone
- Note extent and type of overhanging vegetation and any observed any observed LWD originating in riparian zone. Estimate percent overhead cover in stream thalweg.
- Note and describe extent of vegetation overhanging stream channel, fallen vegetation
- Qualitative evaluation of potential limiting riparian factors such (LWD or shade limitations)

3.1.3 Track B Information

Collect similar information as listed in Track A; however site access will allow for on-site evaluation of the riparian condition based on qualitative and quantitative field data gathered from within the riparian zone.

- Identify shrub or tree species within the riparian zone, including any observed invasive species.
- Estimate or measure canopy cover and ground cover within the riparian zone (Daubenmire, 1959) for dominant species. If measuring, use plots or intercept along a measuring tape.
- Approximate average diameter (diameter breast height – DBH) of trees within riparian zone using representative measurements
- Width and length of functioning riparian zone and
- Riparian interaction with stream banks (e.g., overhanging vegetation, bank stabilization by roots),
- Measure average in-stream riparian cover in the stream thalweg using a densitometer (average riparian cover measured facing upstream, downstream, left bank, and right bank).
- Observations or qualitative evaluation of reach or basin scale limiting riparian factors (such as large-scale LWD or shade limitations).

3.1.4 Track C Information

If the project involves substantial impacts to the riparian corridor, particularly forested riparian areas, it may be necessary to supplement the data collection efforts from above with a more accurate tree survey conducted with GPS survey or professional land survey. Within forested buffer impact areas, detailed survey of the following parameters may be appropriate:

- Tree locations
- Tree species
- Tree diameters
- Estimated tree heights
- Locations of snags and dead/ down woody debris

3.2 Physical In-Stream Habitat

There are literally hundreds of formal assessment protocols prepared for the evaluation of stream environments and habitats. Assessment methods to assess physical in-stream habitat for Pacific Northwest streams are also numerous (e.g. Overton et al. 1997, Pleus and Schuett-Hames 1998, Barbour et al. 1999). In addition, several agencies in the region have developed their own protocols that use unique suites of channel features and channel feature definitions. These protocols generally address measurement of the same in-stream habitat parameters (e.g., woody debris, channel morphology, streambank condition) with varying levels of detail. In order to cover the range of data requirements for both Phase 1 and Phase 2 Sound Transit projects, the discussion of field methods (Tracks A, B and C) for an assessment of this Key Aquatic Habitat Element is focused on these in-stream habitat parameters. Table 4 on page 13 details the specific metrics/measurements that may be applicable for each parameter under Tracks A, B, and C, with recommendations for specific methods or protocols, where appropriate. Table 5 summarizes the methodological references noted in Table 4 for various in-stream habitat parameters.

In addition, other authors have compared and contrasted various protocols and assessments from a nation-wide perspective (Somerville, 2010), with a focus on those assessments prepared for application in the Pacific Northwest region (Johnson et al., 2001; Stolnack et al. 2005). These review documents are excellent sources to consult prior to undertaking a detailed physical habitat assessment, especially in cases where the assessment is focused on specific in-stream habitat parameters.

3.2.1 Background Information

1) Review existing literature on physical in-stream habitat conditions, including stream size (width), presence of LWD and complex habitat features, approximate stream gradient/channel morphology, stream substrate and sediment condition, and bank condition. Reports that may contain information reach or sub-basin scale physical conditions include:
    - The Washington State Conservation Commission Limiting Factors Analysis, organized by Water Resource Inventory area (http://scc.wa.gov/directory/ or http://www.eopugetsound.org/articles/water-resource-inventory-areas-puget-sound)
    - Salmon recovery plans – Puget Sound: http://www.psp.wa.gov/SR_map.php King County: http://www.kingcounty.gov/environment/animalsAndPlants/salmon-and-trout.aspx
    - Shoreline Master Program Inventory reports for local jurisdictions http://www.ecy.wa.gov/programs/sea/shorelines/smp/citizen.html
    - Williams et al. (1975)
    - Local watershed analysis or stream assessment reports

2) Review aerial photographs, topographic maps, and any available site photos.
    - Google Earth – also view past stream habitat conditions using historic photos on site
    - Bing Maps – Birds Eye View feature is useful for assessing some in-stream conditions
    - Digital or hardcopy orthophotos
    - Topographic maps (LIDAR data if available) to determine stream gradients. LIDAR data can be obtained from the Puget Sound LIDAR Consortium at http://pugetsoundlidar.ess.washington.edu/

3) Use the results of 1) and 2) above to describe the following in-stream habitat conditions at the site/stream reach to the extent feasible:
   - general horizontal and vertical channel form (stream gradient and channel morphology) including the presence and quality of pools and riffles and channel confinement/entrenchment
   - dominant in-stream substrates (cobble, gravel, fines, etc.) and general sediment transport dynamics (source, transport, or response reach),
   - presence/absence of LWD, or frequency of LWD (if available),
   - streambanks condition, including bank stability and presence of bank hardening/revetments

3.2.2 Track A Information

After collecting and synthesizing relevant background information on in-stream physical habitat conditions within the project area, conduct a site visit within existing Sound Transit or public right-of-way/easement areas. Provide qualitative descriptions, based on visual observations, of on-site in-stream habitat conditions as detailed in Table 4 on the following page. The primary Channel Geomorphological Units (CGU) used for the assessment will likely be limited to fast/slow habitat types, as the evaluation will be based on visual observations only.

3.2.3 Track B Information

Collect similar information as listed in Track A; however site access will allow for better evaluation of in-stream physical habitat conditions, based on qualitative and quantitative field data gathered from within the stream. Information on specific recommended measurements, including appropriate references, is presented in Table 4. The primary Channel Geomorphological Units (CGU) used for the assessment will likely include a moderate detail (pools, riffles, and runs/glides at a minimum). Pools may be further classified into the type of pool (e.g., lateral scour, medial scour, boulder-formed pocket pool).

3.2.4 Track C Information

If the project involves substantial impacts to in-stream habitat, particularly impacts to the stream bed, stream banks, or local hydraulics, or if the site is to be used for compensatory mitigation, it may be necessary to supplement the data collection efforts from above with more detailed measurements as listed in Table 4.

Table 4. Specific Metrics for Assessment of Physical In-Stream Habitat Parameters

Parameter	**Metric/Measurement**	**Track A – Limited Site Access and Low Impact**	**Track B – Site Access and Moderate Impacts**	**Track C– Site Access and Substantial Impacts OR Site to be Used as Compensatory Mitigation**
Channel Form and Profile	Macrohabitat - habitat type	Visual characterization of Channel Geomorphological Units (CGUs) into slow/fast water habitats.	Classify and measure macrohabitat unit length using classification including pools, riffles, runs, and/or glides. Depending on specific impacts, additional detail may be appropriate (Arend 1999).	Same as Track B. If substantial alteration of stream hydraulics, may be useful to classify and measure CGUs using detailed classification system (Arend 1999).
	Macrohabitat - pool characteristics	Visual observation of water depths of slow/fast water habitat approximate depth.	Measure maximum pool depths and residual pool depths. Classifying pools based on minimum functional pool width/depth (Pleus et al., 1999).	Same as Track B
	Stream Reach Classification	N/A	N/A	If substantial alteration of stream hydraulics, may be useful to use existing geomorphic classification system to classify project reach - Montgomery and Buffington (1998).
	Stream Slope	Estimate stream slope using topographic maps or LIDAR data if available.	Measure using clinometer or auto-level.	Same as Track B. If substantial alteration of stream hydraulics, may be useful to conduct longitudinal profile study.
	Stream Patterns	Visual observation of channel patterns (e.g., sinuous versus straight channel).	Visual observation of channel patterns (e.g., sinuous versus straight channel).	Same as Track B. If substantial alteration of stream hydraulics, may be useful to measure meander length, radius of curvature, sinuosity, and meander belt width.
	Confinement	Visual assessment of channel confinement and entrenchment.	Measure channel confinement/entrenchment. The entrenchment ratio is the ratio of the width of the flood-prone area to the surface width of the bankfull channel. The flood-prone area width is measured at the elevation that corresponds to twice the maximum depth of the bankfull channel.	Same as Track B. If substantial alteration of stream hydraulics, may be useful to survey complete stream cross-section.
	Channel Dimension/Shape	Visual estimation of bankfull width.	Measure average bankfull width and depth in project area.	Same as Track B. If substantial alteration of stream hydraulics, may be useful to survey complete stream cross-section.
Streambank Condition	Stability	Visual observation of nature and extent of unstable banks.	Measure extent of and location of unstable banks with type of instability (slide, slump, slough, etc.).	Same as Track B. If substantial specific impact to this habitat element or the element is crucial to a key design feature, may be useful to use GPS or PLS to survey location of features.
	Bank Hardening/Revetments	Visual observation of nature and extent of bank hardening/revetments.	Measure extent and location of bank hardening/revetments with type of hardening (riprap, earthen, structural, etc.).	Same as Track B. If substantial specific impact to this habitat element or the element is crucial to a key design feature, may be useful to use GPS or PLS to survey location of features.
Substrate/Sediment	Particle Frequency	Visual estimate of dominant and subdominant substrate over project area.	Visually estimate dominant and subdominant substrate within each CGU. Supplement data with pebble counts at representative pool tail outs (Bunte and Abt 2001).	Same as Track B. If substantial alteration of stream hydraulics, may be useful to use grid surface sampling or sub-surface volumetric sampling (Bunte and Abt 2001).
	Percentage of Fine Sediments/Embeddedness	Visual estimate of amount of surface fines in pools.	Visually estimate percentage of surface fines in each pool CGU. Estimate substrate embeddedness in riffles and pools.	Same as Track B. If substantial alteration of stream hydraulics, may be useful to use grid surface sampling or sub-surface volumetric sampling (Bunte and Abt 2001).
Large Woody Debris	LWD Presence, Frequency, and Location	Visual count of observed pieces of woody debris (>6 feet in length and 0.5 feet in diameter).	Measure location and presence of each piece of LWD (>6 feet in length and 0.5 feet in diameter) and debris jams. Relative position of LWD (thalweg center, thalweg edge, bankfull, bankfull edge).	Same as Track B. If substantial alteration of stream hydraulics or LWD composition, may be useful to measure additional parameters, including mapping/GPS of LWD orientation.
	Debris Jams	Visual observations of presence/absence of LWD jams, including approximate location and size of jam.	Measure location and orientation of each LWD jam, including number of pieces of debris in jam.	Same as Track B. If substantial specific impact to this habitat element or the element is crucial to a key design feature, may be useful to use GPS or PLS to survey location of features.
	LWD Size	Visual estimate of LWD size (length and width).	Measure LWD size (length and width) for each piece of LWD.	Same as Track B. If substantial specific impact to this habitat element or the element is crucial to a key design feature, may be useful to use GPS or PLS to survey location of features.
	Age and Type	Visual estimate of LWD age and composition (deciduous or coniferous).	Measure LWD species (coniferous, deciduous, or unknown) and LWD age class (Shuett-Hames et.al., 1999a).	Same as Track B. If substantial specific impact to this habitat element or the element is crucial to a key design feature, may be useful to use GPS or PLS to survey location of features.
Cover and Refuge	Pool quality	Visual observation of relative pool size, location, depth, and cover.	Assess pool quality using a Pool Quality Index (Platts et al. 1983).	Same as Track B
	Undercut banks	Visual observations of presence/absence of undercut banks.	Measure location and presence of undercut banks.	Same as Track B. If substantial specific impact to this habitat element or the element is crucial to a key design feature, may be useful to use GPS or PLS to survey location of features.
	Off-channel/side-channel habitat	Visual observations of presence/absence of off-channel/side-channel habitat, including associated wetlands. Indicate presence of beaver dams or beaver activity within project area.	Include side-channel habitat in channel form and profile, LWD, streambank condition, and sediment measurements. Measure location, area, and water depth of off-channel areas. Record features of beaver dams and associated habitat.	Same as Track B. If substantial specific impact to this habitat element or the element is crucial to a key design feature, may be useful to use GPS or PLS to survey location of features.
	In-stream cover/protection	Visual observation of aquatic macrophytes, habitat boulders, and other in-stream structures providing cover.	Measure location and presence of aquatic macrophytes, habitat boulders, and other in-stream structures providing cover.	Same as Track B

Table 5 below summarizes the methodologies Sound Transit recommends for assessing in-stream habitat parameters.

Table 5. Methodological References for Physical In-Stream Habitat Parameters

Metric/Measurement	**Methodology Reference**
Habitat Unit Classification and Measurement	Arend, K.K. 1999. Macrohabitat Identification. Pages 75-93 *in* M.B. Bain and N.J. Stevenson, editors. Aquatic habitat assessment; common methods. American Fisheries Society. Bethesda, Maryland.
Pool Characteristics • measurement of maximum pool depths and residual pool depths • classification of pools based on minimum functional pool width/depth	Pleus, A. E., D. Shuett-Hames, and L. Bullchild. 1999. TFW Monitoring Program method manual for the habitat unit survey. Prepared for the WA State Dept. of Natural Resources under the Timber, Fish, and Wildlife Agreement. TFW-AM9-99-003. DNR #105. June. 31 pp.
Stream Reach Classification	Montgomery DR, Buffington JM. 1998. Channel Processes, Classification and Response. *In* Naiman, R. and Bilby, R. (Eds) River Ecology and Management: Lessons from the Pacific Coastal Ecoregion, New York, NY: Springer-Verlag.
Sediment Characteristics • Particle Frequency • Percentage of Fine Sediments/Embeddedness	Bunte, K. and Abt. S.R. 2001. Sampling surface and subsurface particle size distributions in wadeable gravel and cobble bed streams for analyses in sediment transport, hydraulics and streambed monitoring. Pool Quality Index	Platts, W. S., W. F. Megahan, and G. W Minshall. 1983. Methods for evaluating stream, riparian, and biotic conditions. Gen. Tech. Rep. INT-138. Ogden, UT: U.S. Department of Agriculture, Forest Service, Intermountain Forest and Range Experiment Station. 70 p. http://www.fs.fed.us/rm/pubs_int/int_gtr138.pdf

3.3 Biological Connectivity

An analysis of biological connectivity and associated fish passage conditions may be a key element of Sound Transit projects, particularly for the creation, reconstruction, or removal of stream crossings (roads or bridges). Fish passage structures are regulated under the Washington State Hydraulic Code (WAC 220-110-170). Therefore, where such actions may occur, it is important to have early coordination with the project design team to determine and coordinate on overall project design and permitting needs.

Any definitive evaluation of fish passage conditions should be conducted using the *Fish Passage Barrier and Surface Water Diversion Screening Assessment and Prioritization Manual* (WDFW, 2009). Likewise, design of stream crossings should utilize the standards and procedures in the WDFW *Water Crossing Design Guidelines* document (Barnard, et al. 2013).

3.3.1 Background Information

Review existing literature on biological connectivity and fish passage conditions, including the presence of any known or potential man-made or natural barriers to fish passage, including type, size, and location of such features. Data sources that may contain information reach or sub-basin scale biological connectivity and fish passage conditions include:

- WDFW Fish Passage Program: Data and Maps http://wdfw.wa.gov/conservation/habitat/fish_passage/data_maps.html
- WSDOT Fish Passage Reports http://www.wsdot.wa.gov/environment/biology/fp/fishpassage.htm#reports
- Topographic maps of stream for assessment of steep downstream reach gradients /natural barriers
- Local watershed analysis or stream assessment reports

3.3.2 Track A Information

After collecting and synthesizing relevant background information on biological connectivity habitat conditions within the project area, conduct a site visit within existing Sound Transit or public right-of-way/easement areas. Provide qualitative descriptions, based on visual observations, of biological connectivity habitat and fish passage conditions, including the following:

- Location and approximate dimensions of structures including length, width, and height
- Type of structures – Culvert, bridge, fishway, weir structure, etc.
- Material of structures - Concrete, stone/rip-rap, aluminum, PVC, etc. Note presence of culvert corrugation and liners
- Approximate size/configuration of structures – For culverts note type of structure (round, box, bottomless box, squash, arch, elliptical, etc.) and whether structure is countersunk
- Approximate condition of structure – Note any deterioration or damage to structure
- Presence of natural streambed material within culvert and estimate of percent of culvert opening affected by sedimentation
- Presence and relative extent of any backwater at culvert inlet
- Presence and height of any perch at culvert outlet
- Presence of any plunge pool at culvert outlet and estimated depth of pool

3.3.3 Track B Information

Collect similar information as listed in Track A, however site access will allow for better evaluation of connectivity and fish passage condition based on qualitative and quantitative field data gathered from within the stream. The use of the Level A Methodology and Field Form from WDFW (2009) is highly recommended for assessment purposes as it will ensure all essential information is captured. In addition to information collected in the Track A analysis on culvert shape, the following data should be recorded per WDFW (2009):

- Measure relative inlet and outlet elevations (preferable) or measured slope of culvert
- Measure culvert dimensions
- Measure stream channel width (bankfull width)
- Measure water surface drop at outfall
- Measure maximum plunge pool depth

3.3.4 Track C Information

If the project involves substantial impacts fish passage structures, particularly the alteration of an existing potential barrier and the Level A Analysis (WDFW, 2009) is not conclusive on barrier status (Level A does not provide conclusive barrier status in all cases), it may be necessary to coordinate with the design team to determine if a Level B analysis is required. This analysis is usually completed by a hydrologist, geomorphologist, or engineer and requires measurement of additional upstream and downstream parameters including channel width, depth, slope, and characterization of bed material. For specific methods, data requirements, and analysis tools, see WDFW (2009).

3.4 Water Quality and Quantity

3.4.1 Background Information

Review existing literature on water quality and flow conditions, including known impairments of water quality and temperature, and stream flow characteristics. Include any information on impairments or limiting factors from the literature or databases. Data sources that may contain information reach or sub-basin scale water quality and flow conditions include:

- Washington Streamflow Data - USGS
  Historic data = http://wa.water.usgs.gov/data/realtime/adr/interactive/
  Realtime data= http://waterdata.usgs.gov/wa/nwis/current?type=flow
- 303(d) list - Washington State Department of Ecology http://www.ecy.wa.gov/programs/wq/303d/
- King County Hydrologic Information Center
  http://green.kingcounty.gov/WLR/Waterres/hydrology/default.aspx
- Streams Water Quality Monitoring Data
  http://green.kingcounty.gov/WLR/Waterres/StreamsData/StreamList.aspx
- Local watershed analysis or stream assessment reports

3.4.2 Track A Information

After collecting and synthesizing relevant background information on water quality and quantity conditions within the project area, conduct a site visit within existing Sound Transit or public right-of-way/easement areas. Provide qualitative description of water quality and flow conditions including the following:

- Note any drainage outfalls, including type/size/location of structure, possible source and volume of outflow during time of site visit.
- Visually estimate streamflow (in cubic feet per second) and stream velocity (feet/second).

3.4.3 Track B and C Information

In almost all cases, the information gathered during the Background Information and Track A investigations will be sufficient to effectively characterize water quality and flow. However, in certain rare circumstances, additional site-specific water quality and flow measurements may be appropriate. As these circumstances are rare, and any such measurements should be tailored to specific project requirements (e.g., permit conditions), such additional measurements are not discussed in this document.

3.5 Fish Presence, Fish Habitat Use, and Stream Typing

There is a difference between fish presence and fish habitat use, and just because fish may not be present at a given time of the year does not mean that a particular stream or stream habitat is not used by fish. Fish presence may respond to seasonal use of a given stream or habitat type as well as a particular life stage of a given fish species. For these reasons, the general best approach is to assume fish habitat use wherever suitable fish habitat exists, and consult with Sound Transit environmental staff before collecting additional data on fish presence.

The determinations of fish habitat use, and the related element of stream typing, are key in determining the potential severity of project impacts, the width of regulated stream buffers, and the requirements for ensuring fish passage at crossing structures. Although for rivers and larger streams, extensive information exists on fish habitat use and stream type, this information is often times lacking for smaller first and second order tributary streams. The following methods utilize an extensive search of background information coupled with measurements of a stream's physical characteristics to evaluate the potential for fish habitat use based on the presence of suitable fish habitat.

3.5.1 Background Information

Review existing literature on fish habitat use and stream typing conditions, including any documented presence of fish species potentially or known to be present. It should also include documented or potentially present suitable fish habitat within the project area. Include any existing stream typing information from the literature or databases. Data sources that may contain information reach or sub-basin scale biological connectivity and fish passage conditions include:

- WDFW Priority Habitats and Species Online Mapper http://apps2.dfw.wa.gov/prodphsontheweb/viewer.aspx?auth=dchBC3QPoGho84hRndFNAyiX2awipVxGmK5mj/T0HbP429kXX73bzQ==
- WDFW SalmonScape Database http://apps.wdfw.wa.gov/salmonscape/
- DNR Water Typing Online Mapper http://www.dnr.wa.gov/businesspermits/topics/forestpracticesapplications/pages/fp_watertyping.aspx
- The Washington State Conservation Commission Limiting Factors Analysis, organized by Water Resource Inventory area (http://scc.wa.gov/directory/ or http://www.eopugetsound.org/articles/water-resource-inventory-areas-puget-sound)
- Wild Fish Conservancy Water Type Assessments and Interactive Maps http://wildfishconservancy.org/resources/maps
- Fish distribution in WRIA 8: http://www.govlink.org/watersheds/8/reports/fish-maps/default.aspx
- A Catalog of Washington Streams and Salmon Utilization (Williams et al., 1975)
- Local jurisdiction Critical/Sensitive Area maps
- Local watershed analysis or stream assessment reports

3.5.2 Track A Information

After collecting and synthesizing relevant background information on fish habitat use and stream typing within the project area, conduct a site visit within existing Sound Transit or public right-of-way/easement areas. Visually observe for the presence of fish. If the background information or visual observation does not clearly indicate fish use status of a particular stream, it may be difficult to determine fish use and therefore stream typing) at a site based upon the direct observation of salmonids. Due to poor visibility, low escapement levels, the existence of human-made barriers, or other factors, fish may not be observed during the field visit.

The Forest Practices Rule (WAC 222-16-031) is used to define water types. Based on the WAC, there are a number of methods to determine if a site has the potential to provide fish habitat. Satisfaction of one or more of the following criteria qualifies a water body as fish bearing or potential fish habitat:

- Watercourses shown by DNR as containing fish on DNR stream typing maps, the WDFW Priority Habitats and Species database, or the WDFW SalmonScape database.
- Watercourses with documented salmonid use determined by visual observation, electrofishing, or verification by local biologists.
- Estimate scour line width. Watercourses having average scour line widths (bankfull widths) in excess of 0.6 meters (2 feet) in Western Washington, provided the stream gradient is less than 20 percent.

Note that seasonally dry streams (ephemeral or intermittent) can provide fish habitat during periods of flow. When evaluating dry stream channels, consider the physical characteristics of the channel and proximity to known fish-bearing water. Also, consider the timing of fish presence for species in the area that may enter the habitat when flow is present. For example, chum salmon often use streams that may only flow for a few months out of the year; they will spawn in the channel during the fall when flow is present and fry will out-migrate in the spring immediately after emergence. In another example, off-channel rearing habitat and floodplain habitat may be used by juvenile salmonids during winter months, even though the channel is dry during the summer.

3.5.3 Track B Information

Better site access will allow for a more comprehensive analysis of evaluation of bankfull width, and greater opportunity to visually observe for fish presence. However, increased site access will not necessarily provide definitive results. If the result of background information and Track A does not provide complete or definitive results, the following options may be considered, as appropriate:

- Request fish use/stream typing assistance from WDFW, Tribal entities, or local government agencies. Assistance may consist of local knowledge of fish distribution or technical assistance with fish presence studies.

- Utilize a qualified fisheries biologist to estimate fish habitat use based on habitat conditions, within, upstream, and downstream of site, noting that absence of fish during a site investigation does not by itself confirm perennial absence.

- If background information indicates a potentially natural downstream fish barrier, conduct downstream reconnaissance to locate and assess natural barrier. Note that lack of fish access for anadromous species does not indicate absence of resident fish species (e.g., resident cutthroat trout or sculpin).

- Watercourses with documented salmonid use determined by visual observation, electrofishing, or verification by local biologists.

3.5.4 Track C Information

In extraordinary circumstances (e.g., this information is tied to a permit condition or the information is crucial for design of a substantial design element such as road or culvert), electrofishing, per the requirements in WAC 220-20-045 can be used to establish fish presence and stream typing. This pathway should only be used under careful consideration and in consultation with WDFW. Electrofishing, or other fish sampling methods, should be pre-approved by Sound Transit environmental staff and conducted by experienced fisheries biologists.

4. Considerations and Limitations

The purpose of this report, including associated flowcharts and tables, is to serve as a guide for assessing streams that are potentially affected by Sound Transit projects. Due to variation in the specific type and severity of project impacts, coupled with property access issues and the unique requirements of multiple regulatory agencies that are commonly involved, it is difficult to craft a "one size fits all" survey protocol. This difficulty is illustrated by an analysis of the stream assessment methods used by two large governmental agencies involved in transportation projects: the Washington State Department of Transportation and the King County Road Services Division. Neither of these agencies has specific stream assessment protocols for determining project impacts. This is also common for most local governments, as a sufficiently broad, detailed, and inclusive stream assessment survey protocol to cover all available project permitting and design needs would be inherently detailed. This in turn can lead to the potential collection of a substantial amount of information, extraneous to the needs of the project, resulting in an increase in project effort and expense.

Therefore, one should consider some project-specific elements prior to assessing streams. This will allow the user to specifically tailor the stream assessment methods in order to both "right size" the analysis methods and to ensure that information is collected in an efficient way that anticipates current and future information needs. These elements can be assessed by asking and answering the following project-specific questions:

- **Which specific habitat elements and sub-elements will be affected (e.g., in-stream substrate, stream banks, riparian zone width, etc.)?** Think carefully about the specific project impacts or mitigation needs and the information that should be collected to compare or assess these impacts or evaluate appropriate mitigation.

- **What project stage or stages is data from the stream assessment to be used -- programmatic planning, alternative comparison, initial permitting, project design, or mitigation design?** The stream assessment should be tailored to a level of detail that addressed the current project planning, design, or permitting phase and that will support the related documents and plans.

- **If the general purpose of the stream assessment is to help compare project options, is this comparison for programmatic options, many specific design alternatives, a small number of design alternatives, or is the purpose to compare a single alternative with a no-build option?** Based on the specific answer, the stream assessment should be tailored to allow for adequate analysis of impacts, without collecting extraneous information. Conversely, if only one site/alignment is being evaluated and access is not limited, collecting more detailed information early on may be beneficial in the long-term, especially if mitigation is necessary.

- **If the purpose of the stream assessment is to compare among a limited number of specific design options, do the alternatives impact stream habitats in similar manners and locations?** If impacts to streams from most or all of the alternatives will occur in the same geographic area(s), more robust initial stream assessment methods may be appropriate in order to minimize multiple assessments during the project lifecycle, thereby maximizing efficiency and limiting costs.

- **What is the project timeframe for alternative comparison, design, and permitting**? Expedited timeframes may require a more robust initial stream assessment method, in order to quickly advance design and permitting, or to avoid the risk of unexpected delay at a late stage of the project.

- **Are other project staff collecting similar or ancillary field data on stream conditions**? It is important to coordinate with other project staff on their data acquisition needs prior to selecting final assessment methods. For example, structural or civil engineers may be performing detailed hydraulic or hydrological analyses within the same stream reaches, and potentially eliminating the need for some channel morphology or sediment data collection during the stream assessment.

Table G3.4-1 Wetland Determination Sample Points

Sample Point	Wetland Determination (wetland/upland)	USFWS Wetland Classification	Vegetation	Soils	Hydrology	Report Notes
SP WFW 1-1	Wetland	PFO	Dominance Test	A12	Secondary: D2, D5	
SP WFW 1-2	Wetland	PFO	Dominance Test	A12	Secondary: D2, D5	
SP WFW 1-3	Upland	n/a	none	none	none	
SP WFW 1-4	Wetland	PEM	Dominance Test	other	Secondary: D2, D5	Hydric Soils rationale: Sample plot nearly meets indicator for F6, Redox Dark Surface. Dark surface layers may have redox that is difficult to see. Given presence of hydrophytic vegetation and geomorphic position below OHWM of East Fork Hylebos Creek, soil is likely seasonally flooded for 14 or more consecutive days during the growing season, and therefore hydric soils presumed to exist.
SP WFW 1-5	Upland	n/a	none	none	none	
SP WFW 1-6	Wetland	PFO	Dominance Test	F6	Primary: B1 Secondary: B9, D2	
SP WFW 1-7	Upland	n/a	none	none	none	
SP WFW 1-8	Wetland	PFO	Dominance Test	Other	Primary: B1 Secondary: D5	Hydric Soils rationale: Sample plot nearly meets redox dark surface. Given presence of water marks in the area and presence of hydrophytic vegetation, it is assumed that the area is inundated for 14 or more consecutive days during growing season and therefore hyric soil is present.
SP WFW 2-1	Wetland	PFO	Rapid Test for Hydrophytic Vegetation	A1	Primary: A1, A2, A3, B1 Secondary: D5	
SP WFW 2-2	Upland	n/a	Dominance Test	none	none	
SP WFW 2-3	Wetland	PFO	Dominance Test	A4, A12	Primary: A2, A3, C1	
SP WFW 2-4	Upland	n/a	none	none	none	
SP WFW 3-1	Wetland	PSS	Dominance Test	F6	Primary: A2, A3	
SP WFW 3-2	Upland	n/a	Dominance Test	none	none	
SP WFW 4-1	Wetland	PSS	Dominance Test	F6	Primary: A2, A3 Secondary: D5	
SP WFW 4-2	Upland	n/a	Dominance Test	none	none	
SP WFW 5-1	Wetland	PFO	Dominance Test	A12	Primary: A1, A2, A3	
SP WFW 5-2	Upland	n/a	none	none	none	
SP WFW 6-1	Wetland	PSS	Dominance Test	F6	Primary: A1, A2, A3	
SP WFW 6-2	Upland	n/a	none	none	none	
WFW-07-SP1	Wetland	PEM	Dominance Test	Other	Primary: A2, A3 Secondary: D2, D5	Hydric Soil Rationale: Soils appear to be a fluvial entisol with an aquic moisture regime. Hydric soils supported by hydrophytic vegetation and strong hydrology indicators.
WFW-07-SP2	Upland	n/a	Dominance Test	none	none	
WFW-07-SP3	Wetland	PSS	Dominance Test	A11, F3	Primary: A3, B2, B3 Secondary: D2, D5	
WFW-07-SP4	Upland	n/a	none	none	none	

Table G3.4-1 Wetland Determination Sample Points (continued)

Sample Point	Wetland Determination (wetland/upland)	USFWS Wetland Classification	Vegetation	Soils	Hydrology	Report Notes
WFW-08-SP1	Wetland	PSS	Dominance Test	Other	Primary: A1, A2, A3, B1 Secondary: D2, D5	Hydric Soil Rationale: Stream has been heavily modified, evidenced by quarry spalls at 4.5 inches below ground surface, and appears to be used as a constructed stormwater facility. Soil appears to be a fluvial entisol with aquic moisture regime. Supported by strong hydrophytic vegetation, geomorphic position on stream bench, significant organics in soils, and strong wetland hydrology indicators
WFW-08-SP2	Upland	n/a	none	none	none	
WFW-08-SP3	Wetland	PEM	Dominance Test	Other	Primary: A2, A3, B1 Secondary: D2, D5	Hydric Soil Rationale: Stream has been heavily modified, evidenced by quarry spalls at 7 inches below ground surface, and appears to be used as a constructed stormwater facility. Soil appears to be a fluvial entisol with aquic moisture regime. Supported by strong hydrophytic vegetation, geomorphic position on stream bench, and strong wetland hydrology indicators.
WFW-09-SP1	Wetland	PSS	Dominance Test	A11 and F3	Primary: A2, A3, C3 Secondary: D2, D5	
WFW-09-SP2	Upland	n/a	Dominance Test	none	Secondary: D5	
WFW-10-SP01	Wetland	PFO	Dominance Test	Other	Primary: A2, A3 Secondary: D2, D5	Hydric Soil Rationale: Soils appear to be a fluvial entisol with an aquic moisture regime. Hydric soils supported by hydrophytic vegetation and strong hydrology indicators.
WFW-10-SP10	Upland	n/a	None	none	none	
WFW-10-SP11	Upland	n/a	none	none	none	
WFW-10-SP12	Wetland	PFO	Dominance Test	Other	Primary: A2, A3 Secondary: D2, D5	Hydric Soil Rationale: Soils appear to be a fluvial entisol with an aquic moisture regime. Hydric soils supported by strong hydrophytic vegetation and strong hydrology indicators.
WFW-10-SP13	Wetland	PFO	Dominance Test	F6	A2, A3	
WFW-10-SP02	Upland	n/a	Dominance Test	none	none	
WFW-10-SP03	Wetland	PFO	Dominance Test	A4, A11	Primary: A2, A3 Secondary: D2	
WFW-10-SP04	Upland	n/a	none	none	none	
WFW-10-SP05	Wetland	PFO	Dominance Test	F6	Primary: A3 Secondary: D2	
WFW-10-SP06	Upland	n/a	Dominance Test	none	none

WETLAND DETERMINATION DATA FORM - Western Mountains, Valleys, and Coast Region

Project/Site: Sound Transit OMFS   City/County: Federal Way, King   Sampling Date: 10/9/2019
Applicant/Owner: Sound Transit   State: WA   Sampling Point: SP FW V1
Investigators: DANIELSKI   Section, Township, Range: T21N R4E S21
Landform (hillslope, terrace, etc.): Depression   Local Relief (concave, convex, none): Concave   Slope(%): 0
Subregion (LRR): A   Lat: 47.292610   Long: -122.305954   Datum: WGS84
Soil Map Unit Name: Alderwood gravelly sandy loam   NWI Classification: UPL
Are climatic / hydrologic conditions on the site typical for this time of year?   Yes ____   No X   (If No, explain in Remarks)
Are Vegetation: ____ Soil ____ or Hydrology ____ significantly disturbed?   Are "Normal Circumstances" present?   Yes X   No ____
Are Vegetation: ____ Soil ____ or Hydrology ____ naturally problematic?   (If needed, explain any answers in Remarks.)

SUMMARY OF FINDINGS - Attach a site map showing sampling point locations, transects, important features, etc.

Hydrophytic Vegetation Present?	Yes X	No		
Hydric Soil Present?	Yes	No X	**Is the Sampled Area**	
Wetland Hydrology Present?	Yes	No X	**within a Wetland?**	Yes ____ No X

Remarks:

Verification plot in salmonberry dominated swale. Sample plot has 1 of 3 wetland indicators, is not located in a wetland. The preceding three months were wetter than normal; however, site visit occurred at end of the dry season so dry season conditions were still considered when evaluating hydrology.

VEGETATION – Use scientific names of plants.

	Absolute % Cover	Dominant Species?	Indicator Status
Tree Statum (Plot size: 5m)			
1.			
2.			
3.			
4.			
		= Total Cover	
Sapling/Shrub Stratum (Plot size: 3m)

3. Rubus ursinus	5	No	FACU
4.			
5.			
	80	= Total Cover	
Herb Stratum (Plot size: 1m)			
1. Tolmiea menziesii	15	Yes	FAC
2.			
3.			
4.			
5.			
6.			
7.			
8.			
9.			
10.			
11.			
	15	= Total Cover	
Woody Vine Stratum (Plot size:)			
1.			
2.			
		= Total Cover	

% Bare Ground in Herb Stratum 85   % Cover of Biotic Crust ____

Dominance Test Worksheet:

Number of Dominant Species That Are OBL, FACW, or FAC:	2	(A)
Total Number of Dominant Species Across All Strata:	2	(B)
Percent of Dominant Species That Are OBL, FACW, or FAC:	100	(A/B)

Prevalence Index worksheet:

Total % Cover of:		Multiply by:		
OBL species		x1=		
FACW species		x2=	0	
FAC species	85	x3=	255	
FACU species	10	x4=	40	
UPL species		x5=	0	
Column Totals:	95	(A)	295	(B)

Prevalence Index = B/A= 3.11

Hydrophytic Vegetation Indicators:

- ____ 1 - Rapid Test for Hydrophytic Vegetation
- X 2 - Dominance Test is >50%
- ____ 3 - Prevalence Index is ≤3.0¹
- ____ 4 - Morphological Adaptations¹ (Provide data in Remarks or on a separate sheet)
- ____ 5 - Wetland Non-Vascular Plants¹
- ____ Problematic Hydrophytic Vegetation¹ (Explain)

¹Indicators of hydric soil and wetland hydrology must be present, unless disturbed or problematic.

Hydrophytic Vegetation Present?   Yes X   No ____

Remarks:

Sample plot meets dominance test but does not meet prevalence index for hydrophytic vegetation.

SOIL

Sampling Point: SP FW V1

Profile Description: (Describe to the depth needed to document the indicator or confirm the absence of indicators.)

Depth	Matrix		Redox Features					
(inches)	Color (moist)	%	Color (moist)	%	Type¹	Loc²	Texture	Remarks
0-14	10YR 3/3	100					Sandy Loam	

¹Type: C= Concentration, D= Depletion, RM=Reduced Matrix, CS=Covered or Coated Sand Grains. ²Location: PL=Pore Lining, M=Matrix.

Hydric Soil Indicators: (Applicable to all LRRs, unless otherwise noted.)

- ☐ Histosol (A1)
- ☐ Histic Epipedon (A2)
- ☐ Black Histic (A3)
- ☐ Hydrogen Sulfide (A4)
- ☐ Depleted Below Dark Surface (A11)
- ☐ Thick Dark Surface (A12)
- ☐ Sandy Mucky Mineral (S1)
- ☐ Sandy Gleyed Matrix (S4)
- ☐ Sandy Redox (S5)
- ☐ Stripped Matrix (S6)
- ☐ Loamy Mucky Mineral (F1) (except MLRLA 1)
- ☐ Loamy Gleyed Matrix (F2)
- ☐ Depleted Matrix (F3)
- ☐ Redox Dark Surface (F6)
- ☐ Depleted Dark Surface (F7)
- ☐ Redox Depressions (F8)

Indicators for Problematic Hydric Soils³:

- ☐ 2 cm Muck (A10)
- ☐ Red Parent Material (TF2)
- ☐ Very Shallow Dark Surface (TF12)
- ☐ Other (Explain in Remarks)

³Indicators of hydrophytic vegetation and wetland hydrology must be present, unless disturbed or problematic.

Restrictive Layer (if present):

Type: ____________

Depth (inches): ____________

Hydric Soil Present? Yes ☐ No X

Remarks:

Sample plot lacks indicators of hydric soil.

HYDROLOGY

Wetland Hydrology Indicators:

Primary Indicators (minimum of one required; check all that apply)

- ☐ Surface Water (A1)
- ☐ High Water Tables (A2)
- ☐ Saturation (A3)
- ☐ Water Marks (B1)
- ☐ Sediment Deposits (B2)
- ☐ Drift Deposits (B3)
- ☐ Algal Mat or Crust (B4)
- ☐ Iron Deposits (B5)
- ☐ Surface Soil Cracks (B6)
- ☐ Inundation Visible on Aeriel Imagery (B
- ☐ Sparsley Vegetated Concave Surface (B8)
- ☐ Water-Stained Leaves (B9) (**except MRLA 1, 2, 4A, and 4B**)
- ☐ Salt Crust (B11)
- ☐ Aquatic Invertebrates (B13)
- ☐ Hydrogen Sulfide Odor (C1)
- ☐ Oxidized Rhizospheres along Living Roots (C3)
- ☐ Presence of Reduced Iron (C4)
- ☐ Recent Iron Reduction in Tilled Soils (C6)
- ☐ Stunted or Stressed Plants (D1) (**LRR A**)
- ☐ Other (Explain in Remarks)

Secondary Indicators (2 or more required)

- ☐ Water Stained Leaves (B9) (**MRLA 1, 2, 4A, and 4B**)
- ☐ Drainage Patterns (B10)
- ☐ Dry-Season Water Table (C2)
- ☐ Saturation Visible on Aeriel Imagery (C9)
- ☐ Geomorphic Position (D2)
- ☐ Shallow Aquitard (D3)
- ☐ FAC-Neutral Test (D5)
- ☐ Raised Ant Mounds (D6) (**LRR A**)
- ☐ Frost-Heave Hummocks (D7)

Field Observations:

Surface Water Present? Yes ☐ No X Depth (inches): ____________

Water Table Present? Yes ☐ No X Depth (inches): ____________

Saturation Present? Yes ☐ No X Depth (inches): ____________
(includes capillary fringe)

Wetland Hydrology Present? Yes ☐ **No** X

Describe Recorded Date (stream gauge, monitoring well, aerial photos, previous inspections), if available:

Remarks:

No primary or secondary wetland hydrology indicators observed.

WETLAND DETERMINATION DATA FORM - Western Mountains, Valleys, and Coast Region

Project/Site: Sound Transit OMFS City/County: Federal Way, King Sampling Date: 10/10/2019
Applicant/Owner: Sound Transit State: WA Sampling Point: SP FW V2
Investigators: STORY, PACE Section, Township, Range: T21N R4E S21
Landform (hillslope, terrace, etc.): Depression Local Relief (concave, convex, none): Concave Slope(%): 0
Subregion (LRR): A - Northwestern Forest, Lat: 47.299988 Long: -122.304810 Datum: WGS84
Soil Map Unit Name: Alderwood gravelly sandy laom NWI Classification: UPL
Are climatic / hydrologic conditions on the site typical for this time of year? Yes ___ No X (If No, explain in Remarks)
Are Vegetation: ___ Soil X or Hydrology ___ significantly disturbed? Are "Normal Circumstances" present? Yes X No ___
Are Vegetation: ___ Soil ___ or Hydrology ___ naturally problematic? (If needed, explain any answers in Remarks.)

SUMMARY OF FINDINGS - Attach a site map showing sampling point locations, transects, important features, etc.

Hydrophytic Vegetation Present?	Yes ___ No X	
Hydric Soil Present?	Yes ___ No X	**Is the Sampled Area**
Wetland Hydrology Present?	Yes ___ No X	**within a Wetland?** Yes ___ No X

Remarks:

Verification plot located in ditch south of S. 336th Street. Sample plot has 0 of 3 wetland indicators, is not located in a wetland. The preceding three months were wetter than normal; however, site visit occurred at end of the dry season so dry season conditions were still considered when evaluating hydrology.

VEGETATION – Use scientific names of plants.

	Absolute % Cover	Dominant Species?	Indicator Status

Column Totals:	48	(A)	165 (B)

Prevalence Index = B/A= 3.44

Hydrophytic Vegetation Indicators:

___ 1 - Rapid Test for Hydrophytic Vegetation
___ 2 - Dominance Test is >50%
___ 3 - Prevalence Index is ≤3.0[1]
___ 4 - Morphological Adaptations[1] (Provide data in Remarks or on a separate sheet)
___ 5 - Wetland Non-Vascular Plants[1]
___ Problematic Hydrophytic Vegetation[1] (Explain)

[1]Indicators of hydric soil and wetland hydrology must be present, unless disturbed or problematic.

Hydrophytic Vegetation Present? Yes ___ No X

Remarks:

Sample plot does not meet dominance test or prevalence index for hydrophytic vegetation.

SOIL

Sampling Point: SP FW V2

Profile Description: (Describe to the depth needed to document the indicator or confirm the absence of indicators.)

Depth	Matrix		Redox Features					
(inches)	Color (moist)	%	Color (moist)	%	Type¹	Loc²	Texture	Remarks
0-16	10YR 3/2	100					Silt Loam	
16-18								Drain rock

¹Type: C= Concentration, D= Depletion, RM=Reduced Matrix, CS=Covered or Coated Sand Grains. ²Location: PL=Pore Lining, M=Matrix.

Hydric Soil Indicators: (Applicable to all LRRs, unless otherwise noted.)

____ Histosol (A1)
____ Histic Epipedon (A2)
____ Black Histic (A3)
____ Hydrogen Sulfide (A4)
____ Depleted Below Dark Surface (A11)
____ Thick Dark Surface (A12)
____ Sandy Mucky Mineral (S1)
____ Sandy Gleyed Matrix (S4)
____ Sandy Redox (S5)
____ Stripped Matrix (S6)
____ Loamy Mucky Mineral (F1) (except MLRLA 1)
____ Loamy Gleyed Matrix (F2)
____ Depleted Matrix (F3)
____ Redox Dark Surface (F6)
____ Depleted Dark Surface (F7)
____ Redox Depressions (F8)

Indicators for Problematic Hydric Soils³:

____ 2 cm Muck (A10)
____ Red Parent Material (TF2)
____ Very Shallow Dark Surface (TF12)
____ Other (Explain in Remarks)

³Indicators of hydrophytic vegetation and wetland hydrology must be present, unless disturbed or problematic.

Restrictive Layer (if present):

Type: ____

Depth (inches): ____

Hydric Soil Present? Yes ____ No X

Remarks:

Sample plot lacks hydric soil indicators. Between horizon 1 and horizon 2 is a layer of geotextile fabric. Swale is clearly constructed and has drain rock liner to move water.

Field Observations:

Surface Water Present? Yes X No ____ Depth (inches): 1.00
Water Table Present? Yes X No ____ Depth (inches): 0.0
Saturation Present? (includes capillary fringe) Yes X No ____ Depth (inches): 0.0

Wetland Hydrology Present? Yes X **No** ____

Describe Recorded Date (stream gauge, monitoring well, aerial photos, previous inspections), if available:

Remarks:

Plot in small side channel, possibly old roadbed. Flooded from recent rains. Sample plot meets primary hydrology indicators for surface water, high water table, and saturation.

WETLAND DETERMINATION DATA FORM - Western Mountains, Valleys, and Coast Region

Project/Site: Sound Transit OMFS City/County: Federal Way, King Sampling Date: 12/19/2019
Applicant/Owner: Sound Transit State: WA Sampling Point: SP FW V6
Investigators: STORY, DANIELSKI Section, Township, Range: T21N R4E S21
Landform (hillslope, terrace, etc.): Channel Local Relief (concave, convex, none): None Slope(%): 0
Subregion (LRR): A Lat: 47.292854 Long: -122.307457 Datum: WGS84
Soil Map Unit Name: Alderwood gravelly sandy loam NWI Classification: UPL
Are climatic / hydrologic conditions on the site typical for this time of year? Yes X No (If No, explain in Remarks)
Are Vegetation: Soil or Hydrology significantly disturbed? Are "Normal Circumstances" present? Yes X No
Are Vegetation: Soil or Hydrology naturally problematic? (If needed, explain any answers in Remarks.)

SUMMARY OF FINDINGS - Attach a site map showing sampling point locations, transects, important features, etc.

Hydrophytic Vegetation Present?	Yes X	No		
Hydric Soil Present?	Yes	No X	**Is the Sampled Area**	
Wetland Hydrology Present?	Yes X	No	**within a Wetland?**	Yes No X

Remarks:

Sample plot lacks hydric soil and is not located within a wetland. Site visit occurred outside of growing season.

VEGETATION – Use scientific names of plants.

	Absolute % Cover	Dominant Species?	Indicator Status

Other (Explain in Remarks)

³Indicators of hydrophytic vegetation and wetland hydrology must be present, unless disturbed or problematic.

Restrictive Layer (if present):

Type:
Depth (inches):

Hydric Soil Present? Yes X No

Remarks:

Sample plot meets hydric soil indicator A12, thick dark surface.

HYDROLOGY

Wetland Hydrology Indicators:

Primary Indicators (minimum of one required; check all that apply)

Surface Water (A1)
High Water Tables (A2)
Saturation (A3)
Water Marks (B1)
Sediment Deposits (B2)
Drift Deposits (B3)
Algal Mat or Crust (B4)
Iron Deposits (B5)
Surface Soil Cracks (B6)
Inundation Visible on Aeriel Imagery (B
Sparsley Vegetated Concave Surface (B8)

Water-Stained Leaves (B9) (**except MRLA 1, 2, 4A, and 4B**)
Salt Crust (B11)
Aquatic Invertebrates (B13)
Hydrogen Sulfide Odor (C1)
Oxidized Rhizospheres along Living Roots (C3)
Presence of Reduced Iron (C4)
Recent Iron Reduction in Tilled Soils (C6)
Stunted or Stressed Plants (D1) (**LRR A**)
Other (Explain in Remarks)

Secondary Indicators (2 or more required)

Water Stained Leaves (B9) (**MRLA 1, 2, 4A, and 4B**)
Drainage Patterns (B10)
Dry-Season Water Table (C2)
Saturation Visible on Aeriel Imagery (C9)
X Geomorphic Position (D2)
Shallow Aquitard (D3)
X FAC-Neutral Test (D5)
Raised Ant Mounds (D6) (**LRR A**)
Frost-Heave Hummocks (D7)

Field Observations:

Surface Water Present? Yes ____ No X Depth (inches):
Water Table Present? Yes ____ No X Depth (inches):
Saturation Present? Yes ____ No X Depth (inches):
(includes capillary fringe)

Wetland Hydrology Present? Yes X **No**

Describe Recorded Date (stream gauge, monitoring well, aerial photos, previous inspections), if available:

Remarks:

Sample plot located in forested area. No primary indicators observed, roughly 6 feet from OHWM of Hylebos Creek. Sample plot meets secondary hydrology indicators for FAC-Neutral Test (D5) and Geomorphic Position (D2).

WETLAND DETERMINATION DATA FORM - Western Mountains, Valleys, and Coast Region

- ☐ Raised Ant Mounds (D6) (**LRR A**)
- ☐ Frost-Heave Hummocks (D7)

Field Observations:

Surface Water Present? Yes ☐ No ☒ Depth (inches):

Water Table Present? Yes ☐ No ☒ Depth (inches):

Saturation Present? Yes ☐ No ☒ Depth (inches):
(includes capillary fringe)

Wetland Hydrology Present? Yes ☐ **No** ☒

Describe Recorded Date (stream gauge, monitoring well, aerial photos, previous inspections), if available:

Remarks:

No primary or secondary wetland hydrology indicators observed.

WETLAND DETERMINATION DATA FORM - Western Mountains, Valleys, and Coast Region

Project/Site: Sound Transit OMFS
City/County: Federal Way, King
Sampling Date: 10/9/2019
Applicant/Owner: Sound Transit
State: WA
Sampling Point: SP WFW 1-6
Investigators: DANIELSKI, STORY
Section, Township, Range: T21N R4E S21
Landform (hillslope, terrace, etc.): Flat
Local Relief (concave, convex, none): None
Slope(%): 0
Subregion (LRR): A - Northwestern Forest,
Lat: 47.296963
Long: -122.304909
Datum: WGS84
Soil Map Unit Name: Alderwood gravelly sandy loam
NWI Classification: PFO
Are climatic / hydrologic conditions on the site typical for this time of year? Yes ____ No X (If No, explain in Remarks)
Are Vegetation: ____ Soil ____ or Hydrology ____ significantly disturbed?
Are "Normal Circumstances" present? Yes X No ____
Are Vegetation: ____ Soil ____ or Hydrology ____ naturally problematic?
(If needed, explain any answers in Remarks.)

SUMMARY OF FINDINGS - Attach a site map showing sampling point locations, transects, important features, etc.

Hydrophytic Vegetation Present? Yes X No ____
Hydric Soil Present? Yes X No ____
Wetland Hydrology Present? Yes X No ____

Is the Sampled Area within a Wetland? Yes X No ____

Remarks:

The preceding three months were wetter than normal; however, site visit occurred at end of the dry season so dry season conditions were still considered when evaluating hydrology. Sample plot meets 3 of 3 wetland criteria, is located in WFW-1.

VEGETATION – Use scientific names of plants.

Hydric Soil Indicators: (Applicable to all LRRs, unless otherwise noted.)

- X Histosol (A1)
- Histic Epipedon (A2)
- Black Histic (A3)
- Hydrogen Sulfide (A4)
- Depleted Below Dark Surface (A11)
- Thick Dark Surface (A12)
- Sandy Mucky Mineral (S1)
- Sandy Gleyed Matrix (S4)
- Sandy Redox (S5)
- Stripped Matrix (S6)
- Loamy Mucky Mineral (F1) (except MLRLA 1)
- Loamy Gleyed Matrix (F2)
- Depleted Matrix (F3)
- Redox Dark Surface (F6)
- Depleted Dark Surface (F7)
- Redox Depressions (F8)

Indicators for Problematic Hydric Soils³:

- 2 cm Muck (A10)
- Red Parent Material (TF2)
- Very Shallow Dark Surface (TF12)
- Other (Explain in Remarks)

³Indicators of hydrophytic vegetation and wetland hydrology must be present, unless disturbed or problematic.

Restrictive Layer (if present):

Type:

Depth (inches):

Hydric Soil Present? Yes X No

Remarks:

Sample plot meets hydric soil indicator A1, Histosol.

HYDROLOGY

Wetland Hydrology Indicators:

Primary Indicators (minimum of one required; check all that apply)

- X Surface Water (A1)
- X High Water Tables (A2)
- X Saturation (A3)
- X Water Marks (B1)
- Sediment Deposits (B2)
- Drift Deposits (B3)
- Algal Mat or Crust (B4)
- Iron Deposits (B5)
- Surface Soil Cracks (B6)
- Inundation Visible on Aeriel Imagery (B
- Sparsley Vegetated Concave Surface (B8)
- Water-Stained Leaves (B9) (**except MRLA 1, 2, 4A, and 4B**)
- Salt Crust (B11)
- Aquatic Invertebrates (B13)
- Hydrogen Sulfide Odor (C1)
- Oxidized Rhizospheres along Living Roots (C3)
- Presence of Reduced Iron (C4)
- Recent Iron Reduction in Tilled Soils (C6)
- Stunted or Stressed Plants (D1) (**LRR A**)
- Other (Explain in Remarks)

Secondary Indicators (2 or more required)

- Water Stained Leaves (B9) (**MRLA 1, 2, 4A, and 4B**)
- Drainage Patterns (B10)
- Dry-Season Water Table (C2)
- Saturation Visible on Aeriel Imagery (C9)
- Geomorphic Position (D2)
- Shallow Aquitard (D3)
- X FAC-Neutral Test (D5)
- Raised Ant Mounds (D6) (**LRR A**)
- Frost-Heave Hummocks (D7)

Field Observations:

Surface Water Present? Yes X No Depth (inches): 0.50

Water Table Present? Yes X No Depth (inches): 0.0

Saturation Present? Yes X No Depth (inches): 0.0

(includes capillary fringe)

Wetland Hydrology Present? Yes X **No**

Describe Recorded Date (stream gauge, monitoring well, aerial photos, previous inspections), if available:

Remarks:

Sample plot meets primary hydrology indicators for Surface Water (A1), High Water Table (A2), Saturation (A3), and Water Marks (B1) and secondary hydrology indicator for FAC-Neutral Test (D5)..

WETLAND DETERMINATION DATA FORM - Western Mountains, Valleys, and Coast Region

Project/Site: Sound Transit OMFS City/County: Federal Way, King Sampling Date: 10/16/2019
Applicant/Owner: Sound Transit State: WA Sampling Point: SP WFW 2-2
Investigators: STORY, PACE Section, Township, Range: T21N R4E S21
Landform (hillslope, terrace, etc.): Flat Local Relief (concave, convex, none): Convex Slope(%): 15
Subregion (LRR): A - Northwestern Forest, Lat: 47.299557 Long: -122.312218 Datum: WGS84
Soil Map Unit Name: Tukwila muck NWI Classification: UPL
Are climatic / hydrologic conditions on the site typical for this time of year? Yes ___ No X (If No, explain in Remarks)
Are Vegetation: ___ Soil X or Hydrology ___ significantly disturbed? Are "Normal Circumstances" present? Yes X No ___
Are Vegetation: ___ Soil ___ or Hydrology ___ naturally problematic? (If needed, explain any answers in Remarks.)

SUMMARY OF FINDINGS - Attach a site map showing sampling point locations, transects, important features, etc.

Hydrophytic Vegetation Present?	Yes X	No	
Hydric Soil Present?	Yes	No X	**Is the Sampled Area**
Wetland Hydrology Present?	Yes	No X	**within a Wetland?** Yes ___ No X

Remarks:

On constructed fill berm upslope from boundary. Sample plot has 1 of 3 wetland criteria, is not located in a wetland. Paired upland plot for WFW 2-1. Conditions wetter than normal for time of year.

VEGETATION – Use scientific names of plants.

	Absolute % Cover	Dominant Species?	Indicator Status

Loamy Gleyed Matrix (F2)
Depleted Matrix (F3)
Redox Dark Surface (F6)
Depleted Dark Surface (F7)
Redox Depressions (F8)

Indicators for Problematic Hydric Soils³:

2 cm Muck (A10)
Red Parent Material (TF2)
Very Shallow Dark Surface (TF12)
Other (Explain in Remarks)

³Indicators of hydrophytic vegetation and wetland hydrology must be present, unless disturbed or problematic.

Restrictive Layer (if present):

Type:

Depth (inches):

Hydric Soil Present? Yes X No

Remarks:

Sample plot meets hydric soil indicator A12, Thick Dark Surface.

HYDROLOGY

Wetland Hydrology Indicators:

Primary Indicators (minimum of one required; check all that apply)

X Surface Water (A1)
X High Water Tables (A2)
X Saturation (A3)
Water Marks (B1)
Sediment Deposits (B2)
Drift Deposits (B3)
Algal Mat or Crust (B4)
Iron Deposits (B5)
Surface Soil Cracks (B6)
Inundation Visible on Aeriel Imagery (B
Sparsley Vegetated Concave Surface (B8)

Water-Stained Leaves (B9) (**except MRLA 1, 2, 4A, and 4B**)
Salt Crust (B11)
Aquatic Invertebrates (B13)
Hydrogen Sulfide Odor (C1)
Oxidized Rhizospheres along Living Roots (C3)
Presence of Reduced Iron (C4)
Recent Iron Reduction in Tilled Soils (C6)
Stunted or Stressed Plants (D1) (**LRR A**)
Other (Explain in Remarks)

Secondary Indicators (2 or more required)

Water Stained Leaves (B9) (**MRLA 1, 2, 4A, and 4B**)
Drainage Patterns (B10)
Dry-Season Water Table (C2)
Saturation Visible on Aeriel Imagery (C9)
Geomorphic Position (D2)
Shallow Aquitard (D3)
FAC-Neutral Test (D5)
Raised Ant Mounds (D6) (**LRR A**)
Frost-Heave Hummocks (D7)

Field Observations:

Surface Water Present? Yes X No Depth (inches): 2.00
Water Table Present? Yes X No Depth (inches): 0.0
Saturation Present? Yes X No Depth (inches): 0.0
(includes capillary fringe)

Wetland Hydrology Present? Yes X **No**

Describe Recorded Date (stream gauge, monitoring well, aerial photos, previous inspections), if available:

Remarks:

Sample plot meets primary hydrology indicators for Surface Water (A1), High Water Table (A2), and Saturation (A3).

WETLAND DETERMINATION DATA FORM - Western Mountains, Valleys, and Coast Region

Project/Site: Sound Transit OMFS City/County: Federal Way, King Sampling Date: 10/23/2019
Applicant/Owner: Sound Transit State: WA Sampling Point: SP WFW 5-2
Investigators: STORY, PACE Section, Township, Range: T21N R4E S21
Landform (hillslope, terrace, etc.): Toeslope Local Relief (concave, convex, none): Convex Slope(%): 2
Subregion (LRR): A - Northwestern Forest, Lat: 47.291729 Long: -122.307503 Datum: WGS84

Project No.: 554-1800-019 and -030

SOIL

Sampling Point: **WFW-07-SP1**

Profile Description (Describe to the depth needed to document the indicator or confirm the absence of indicators):

Depth	Matrix		Redox Features					
(inches)	Color (moist)	%	Color (moist)	%	Type[1]	Loc[2]	Texture[3]	Remarks
0-4	10YR 2/2	100					L	
4-7	2.5Y 3/1	100					L	
7-9	5Y 4/1	100					SaL	decaying grass
9-20	10YR 4/1	100					CL	

[1] Type: C=Concentration, D=Depletion, RM=Reduced Matrix, CS=Covered or Coated Sand Grains. [2] Location: PL=Pore Lining, M=Matrix.

[3] Texture: Sa = sand; Si = silt; C = clay; L = loam or loamy. Texture Modifier: co = coarse; f = fine; vf = very fine; + = heavy (more clay); - = light (less clay)

Hydric Soil Indicators (Applicable to all LRRs, unless otherwise noted):

___ Histosol (A1)
___ Histic Epipedon (A2)
___ Black Histic (A3)
___ Hydrogen Sulfide (A4)
___ Depleted Below Dark Surface (A11)
___ Thick Dark Surface (A12)
___ Sandy Mucky Mineral (S1)
___ Sandy Gleyed Matrix (S4)
___ Sandy Redox (S5)
___ Stripped Matrix (S6)
___ Loamy Mucky Mineral (F1) (except MLRA 1)
___ Loamy Gleyed Matrix (F2)
___ Depleted Matrix (F3)
___ Redox Dark Surface (F6)
___ Depleted Dark Surface (F7)
___ Redox Depressions (F8)

Indicators for Problematic Hydric Soils[3]:

___ 2 cm Muck (A10)
___ Red Parent Material (TF2)
___ Very Shallow Dark Surface (TF12)
X Other (Explain in Remarks)

[3] Indicators of hydrophytic vegetation and wetland hydrology must be present, unless disturbed or problematic.

Restrictive Layer (if present):

Type: None
Depth (inches): N/A

Hydric Soil Present? Yes X No ___

Remarks:
Assumed to be hydric based on aquic moisture regime and fluvial entisol. Decaying grass thoughout layers, proximity to floodplain may explain lack of hydric soil indicators

Hydrophytic Vegetation Present?	Yes X	No ____	**Is the Sampled Area within a Wetland?** **Yes X** **No ____**
Hydric Soil Present?	Yes X	No ____	
Wetland Hydrology Present?	Yes X	No ____	

Precipitation:
According to the Seattle Tacoma International NOAA weather station. Precipitation was above the normal range for the three months prior to the site visit.

Remarks:
PSS SP for WFW-07. Located near pedestrian bridge ~2m east and upslope of E. Fork Hylebos Creek Tributary 0016A. The stream has been heavily modified and is adjacent to a golf course.
Vegetation within the wetland and also adjacent upland is dominated by the aggressive species, English ivy (Hedera helix), which would be considered problematic vegetation.
Hydric soil indicators and hydrology indicators are both strong, supporting the assumption that vegetation is also hydric.

Are climatic / hydrologic conditions on the site typical for this time of year? Yes ____ No X (If no, explain in Remarks)
Are Vegetation ____, Soil ____, or Hydrology ____ significantly disturbed? Are "Normal Circumstances" present? Yes X No ____
Are Vegetation ____, Soil X, or Hydrology ____ naturally problematic? (If needed, explain any answers in Remarks.)

SUMMARY OF FINDINGS – Attach site map showing sampling point locations, transects, important features, etc.

Hydrophytic Vegetation Present?	Yes X	No	**Is the Sampled Area within a Wetland?**	**Yes X** **No**
Hydric Soil Present?	Yes X	No		
Wetland Hydrology Present?	Yes X	No		

Precipitation:
According to the Seattle Tacoma International NOAA weather station, precipitation was above the normal range for the three months prior to the site visit.

Remarks:
PSS wetland SP for WFW-08. In SW section of wetland. Wetland is adjacent to E. Fork Hylebos Creek Trib 0016A. The stream is heavily modified and appears to be used as a constructed stormwater facility.
Problematic Soil: Soil appears to be a fluvial entisol with aquic moisture regime. Strong hydrophytic vegetation, geomorphic position on stream bench, significant organics in soils, and strong wetland hydrology indicators support determination as hydric soil.

Sampling Point: **WFW-09-SP1**

Profile Description (Describe to the depth needed to document the indicator or confirm the absence of indicators):

Depth	Matrix		Redox Features					
(inches)	Color (moist)	%	Color (moist)	%	Type[1]	Loc[2]	Texture[3]	Remarks
0-5	10YR 2/2	100					CL	
5-10	10YR 4/1	95	10YR 5/8	5	C	M	CL	
10-16	5Y 5/2	70	7.5YR 4/4	30	C	PL	CL	

[1] Type: C=Concentration, D=Depletion, RM=Reduced Matrix, CS=Covered or Coated Sand Grains. [2] Location: PL=Pore Lining, M=Matrix.

[3] Texture: Sa = sand; Si = silt; C = clay; L = loam or loamy. Texture Modifier: co = coarse; f = fine; vf = very fine; + = heavy (more clay); - = light (less clay)

Hydric Soil Indicators (Applicable to all LRRs, unless otherwise noted):

☐ Histosol (A1)
☐ Histic Epipedon (A2)
☐ Black Histic (A3)
☐ Hydrogen Sulfide (A4)
☒ Depleted Below Dark Surface (A11)
☐ Thick Dark Surface (A12)
☐ Sandy Mucky Mineral (S1)
☐ Sandy Gleyed Matrix (S4)

☐ Sandy Redox (S5)
☐ Stripped Matrix (S6)
☐ Loamy Mucky Mineral (F1) (except MLRA 1)
☐ Loamy Gleyed Matrix (F2)
☒ Depleted Matrix (F3)
☐ Redox Dark Surface (F6)
☐ Depleted Dark Surface (F7)
☐ Redox Depressions (F8)

Indicators for Problematic Hydric Soils[3]:

☐ 2 cm Muck (A10)
☐ Red Parent Material (TF2)
☐ Very Shallow Dark Surface (TF12)
☐ Other (Explain in Remarks)

[3] Indicators of hydrophytic vegetation and wetland hydrology must be present, unless disturbed or problematic.

Restrictive Layer (if present):

Type: none
Depth (inches): n/a

Hydric Soil Present? Yes X No ____

Remarks:
redox features along living roots between 10-16" BGS.

HYDROLOGY

Wetland Hydrology Indicators:

Primary Indicators (minimum of one required; check all that apply)

☐ Surface Water (A1)
☒ High Water Table (A2)
☒ Saturation (A3)
☐ Water Marks (B1)
☐ Sediment Deposits (B2)
☐ Drift Deposits (B3)
☐ Algal Mat or Crust (B4)
☐ Iron Deposits (B5)
☐ Surface Soil Cracks (B6)
☐ Inundation Visible on Aerial Imagery (B7)
☐ Sparsely Vegetated Concave Surface (B8)

☐ Water-Stained Leaves (B9) (except MLRA 1, 2, 4A, and 4B)
☐ Salt Crust (B11)
☐ Aquatic Invertebrates (B13)
☐ Hydrogen Sulfide Odor (C1)
☒ Oxidized Rhizospheres along Living Roots (C3)
☐ Presence of Reduced Iron (C4)
☐ Recent Iron Reduction in Tilled Soils (C6)
☐ Stunted or Stressed Plants (D1) (LRR A)
☐ Other (Explain in Remarks)

Secondary Indicators (2 or more required)

☐ Water-Stained Leaves (B9) (MLRA 1, 2, 4A, and 4B)
☐ Drainage Patterns (B10)
☐ Dry-Season Water Table (C2)
☐ Saturation Visible on Aerial Imagery (C9)
☒ Geomorphic Position (D2)
☐ Shallow Aquitard (D3)
☒ FAC-Neutral Test (D5)
☐ Raised Ant Mounds (D6) (LRR A)
☐ Frost-Heave Hummocks (D7)

Remarks:

WETLAND DETERMINATION DATA FORM – Western Mountains, Valleys, and Coast Region

Project/Site: OMFS and TDLE City/County: Federal Way, King County Sampling Date: 11/1/2019
Applicant/Owner: Sound Transit State: WA Sampling Point: **WFW-10-SP01**
Investigator(s): A. Hoenig, A. Thom Section, Township, Range: T21N R04E S16
Landform (hillslope, terrace, etc.): Hillslope Local relief (concave, convex, none): concave Slope (%): None
Subregion (LRR): Northwest Forests and Coast (LRR A)) Lat: 47.305663 Long: -122.303589 Datum: NAD 1983
Soil Unit (Name-ID-Hydric Rating): Alderwood gravelly sandy loam, 0 to 8 % slopes - AgB - Not Hydric NWI classification: none
Are climatic / hydrologic conditions on the site typical for this time of year? Yes ___ No X (If no, explain in Remarks)
Are Vegetation ___, Soil ___, or Hydrology ___ significantly disturbed? Are "Normal Circumstances" present? Yes X No ___
Are Vegetation ___, Soil ___, or Hydrology ___ naturally problematic? (If needed, explain any answers in Remarks.)

SUMMARY OF FINDINGS – Attach site map showing sampling point locations, transects, important features, etc.

Hydrophytic Vegetation Present?	Yes X	No	
Hydric Soil Present?	Yes X	No	**Is the Sampled Area**
Wetland Hydrology Present?	Yes X	No	**within a Wetland?** **Yes** X **No**

Precipitation:
According to the Seattle Tacoma International NOAA weather station, precipitation was above the normal range for the three months prior to the site visits in November and within the normal range for visits within December. The month of November was drier than normal, and December was wetter than normal.

Remarks:
PFO wetland SP in WFW-10, Unit B. Located west of E. Fork Hylebos Creek Trib 0016A (left bank).

SOIL

Sampling Point: **WFW-10-SP01**

Profile Description (Describe to the depth needed to document the indicator or confirm the absence of indicators):

Depth	Matrix		Redox Features					
(inches)	Color (moist)	%	Color (moist)	%	Type[1]	Loc[2]	Texture	Remarks
0-11	10YR 2/2	100					L	some OM
11-16	10YR 3/2	100					GrL	gravel

[1]Type: C=Concentration, D=Depletion, RM=Reduced Matrix, CS=Covered or Coated Sand Grains. [2]Location: PL=Pore Lining, M=Matrix.

[3]Texture: S = sand; Si = silt; C = clay; L = loam or loamy. Texture Modifier: co = coarse; f = fine; vf = very fine; + = heavy (more clay); - = light (less clay)

Hydric Soil Indicators (Applicable to all LRRs, unless otherwise noted):

☐ Histosol (A1)
☐ Histic Epipedon (A2)
☐ Black Histic (A3)
☐ Hydrogen Sulfide (A4)
☐ Depleted Below Dark Surface (A11)
☐ Thick Dark Surface (A12)
☐ Sandy Mucky Mineral (S1)
☐ Sandy Gleyed Matrix (S4)
☐ Sandy Redox (S5)
☐ Stripped Matrix (S6)
☐ Loamy Mucky Mineral (F1) (except MLRA 1)
☐ Loamy Gleyed Matrix (F2)
☐ Depleted Matrix (F3)
☐ Redox Dark Surface (F6)
☐ Depleted Dark Surface (F7)
☐ Redox Depressions (F8)

Indicators for Problematic Hydric Soils[3]:

☐ 2 cm Muck (A10)
☐ Red Parent Material (TF2)
☐ Very Shallow Dark Surface (TF12)
X Other (Explain in Remarks)

[3]Indicators of hydrophytic vegetation and wetland hydrology must be present, unless disturbed or problematic.

Restrictive Layer (if present):

Type: none
Depth (inches): n/a

Hydric Soil Present? **Yes** X **No** ___

Remarks:
SP located within the floodplain of a stream. Strong hydrophytic vegetation and wetland hydrology support determination of wetland area. Fluvial entisol with aquic moisture regime.

HYDROLOGY

Hydrophytic Vegetation Present?	Yes X	No	**Is the Sampled Area within a Wetland?** **Yes** X **No**
Hydric Soil Present?	Yes X	No	
Wetland Hydrology Present?	Yes X	No	

Precipitation:
According to the Seattle Tacoma International NOAA weather station, precipitation was normal for the three months prior to the site visits in Janurary. The month of Decement was wet, November was dry and October was normal.

Remarks:
WFW10-Unit C. Emergent sample point within PFO wetland vegetation unit. Located on right bank within floodplain near E. Hylebos RB401 OHWM flag, 3m north of double culvert within OHWLs.
Problematic Soil: lack of indicators but appears to be a fluvial entisol with aquic moisture regime. Geomorphic position, strong hydrophytic vegetation and wetland hydrology support determination of wetland area.

____ Redox Depressions (F8)

Indicators for Problematic Hydric Soils[3]:

____ 2 cm Muck (A10)
____ Red Parent Material (TF2)
____ Very Shallow Dark Surface (TF12)
____ Other (Explain in Remarks)

[3]Indicators of hydrophytic vegetation and wetland hydrology must be present, unless disturbed or problematic.

Restrictive Layer (if present):

Type: none
Depth (inches): n/a

Hydric Soil Present? Yes ____ No X

Remarks:
No redoximorphic features were detected. No assumption of hydric soil because only supported by moderate hydrophytic vegetation but lacks wetland hydrology and geomorphic position.

HYDROLOGY

Wetland Hydrology Indicators:

Primary Indicators (minimum of one required; check all that apply)

____ Surface Water (A1)
____ High Water Table (A2)
____ Saturation (A3)

State: WA
Sampling Point: **WFW-15-SP5**
Investigator(s): Kaylee Moser, Aaron Thom
Section, Township, Range: T21N R04E S16 SWSW
Landform (hillslope, terrace, etc.): Depression
Local relief (concave, convex, none): concave
Slope (%): None
Subregion (LRR): Northwest Forests and Coast (LRR A)
Lat: 47.300845
Long: -122.303938
Datum: NAD 1983 (HARN)
Soil Unit (Name-ID-Hydric Rating): Alderwood gr sandy loam, 0 to 8% slopes - 5 - Not Hydric
NWI classification: None
Are climatic / hydrologic conditions on the site typical for this time of year? Yes ____ No X (If no, explain in Remarks)
Are Vegetation no , Soil no , or Hydrology no significantly disturbed?
Are "Normal Circumstances" present? Yes X No ____
Are Vegetation no , Soil no , or Hydrology no naturally problematic?
(If needed, explain any answers in Remarks.)

SUMMARY OF FINDINGS – Attach site map showing sampling point locations, transects, important features, etc.

	Yes	No
Hydrophytic Vegetation Present?	X	
Hydric Soil Present?	X	
Wetland Hydrology Present?	X	

Is the Sampled Area within a Wetland? **Yes** X **No** ____

Precipitation:
According to the Seattle Tacoma Airport NOAA weather station, precipitation was below the normal range for the three months prior to the site visit.

Remarks:
PFO wetland SP. Paired with upland SP WFW-15-SP4. Sampling point is located in a linear depression that was dry at the time of the site visit. Water stained leaves and low vegetation cover was observed indicating seasonal ponding.

WETLAND DETERMINATION DATA FORM – Western Mountains, Valleys, and Coast Region

Project/Site: OMFS and TDLE City/County: Federal Way, King County Sampling Date: 3/2/2020
Applicant/Owner: Sound Transit State: WA Sampling Point: **WFW-16-SP3**
Investigator(s): Kaylee Moser, Adam Thom Section, Township, Range: T21N R04E S16
Landform (hillslope, terrace, etc.): Hillslope Local relief (concave, convex, none): none Slope (%): 3-5%
Subregion (LRR): Northwest Forests and Coast (LRR A)) Lat: 47.313112 Long: -122.299995 Datum: NAD 1983
Soil Unit (Name-ID-Hydric Rating): Arents, Alderwood material, 6 to 15 percent slopes - AmC - Not Hydric NWI classification: none
Are climatic / hydrologic conditions on the site typical for this time of year? Yes ___ No X (If no, explain in Remarks)
Are Vegetation No , Soil No , or Hydrology No significantly disturbed? Are "Normal Circumstances" present? Yes X No ___
Are Vegetation No , Soil No , or Hydrology No naturally problematic? (If needed, explain any answers in Remarks.)

SUMMARY OF FINDINGS – Attach site map showing sampling point locations, transects, important features, etc.

Hydrophytic Vegetation Present?	Yes X	No
Hydric Soil Present?	Yes X	No
Wetland Hydrology Present?	Yes X	No

Is the Sampled Area within a Wetland? **Yes** X **No** ___

Precipitation:
According to the Seattle Tacoma International NOAA weather station, precipitation was above the normal range for the three months prior to the site visits in March.

Remarks:
PSS wetland SP. SP located north of NE park and ride parking lot and ~100ft west of tower

Soil Unit (Name-ID-Hydric Rating): Alderwood gr sandy loam, 0 to 8% slopes - 5 - Not Hydric NWI classification: None
Are climatic / hydrologic conditions on the site typical for this time of year? Yes ___ No X (If no, explain in Remarks)
Are Vegetation no , Soil no , or Hydrology no significantly disturbed? Are "Normal Circumstances" present? Yes X No ___
Are Vegetation no , Soil no , or Hydrology no naturally problematic? (If needed, explain any answers in Remarks.)

SUMMARY OF FINDINGS – Attach site map showing sampling point locations, transects, important features, etc.

Hydrophytic Vegetation Present?	Yes X	No
Hydric Soil Present?	Yes X	No
Wetland Hydrology Present?	Yes	No X

Is the Sampled Area within a Wetland? **Yes** ___ **No** X

Precipitation:
According to the Seattle Tacoma Airport NOAA weather station, precipitation was below the normal range for the three months prior to the site visit.

Remarks:
Flat area near fenceline upslope of WFW-32-SP1. Upland SP paired with WFW-32-SP2.

___ 5 - Wetland Non-Vascular Plants[1]
___ Problematic Hydrophytic Vegetation (Explain)[1]

[1] Indicators of hydric soil and wetland hydrology must be present.

Hydrophytic Vegetation Present? Yes X No ___

Remarks:

SOIL

Sampling Point: **WFW-32-SP2**

Profile Description (Describe to the depth needed to document the indicator or confirm the absence of indicators):

Depth	Matrix		Redox Features					
(inches)	Color (moist)	%	Color (moist)	%	Type[1]	Loc[2]	Texture[3]	Remarks
0-9	10YR 2/2	100					GrSaL	
9-16	2.5Y 6/1	99	10YR 5/6	1	C	M	GrSaL	with cobble

[1]Type: C=Concentration, D=Depletion, RM=Reduced Matrix, CS=Covered or Coated Sand Grains. [2]Location: PL=Pore Lining, M=Matrix.

[3]Texture: Sa = sand; Si = silt; C = clay; L = loam or loamy. Texture Modifier: co = coarse; f = fine; vf = very fine; + = heavy (more clay); - = light (less clay)

Hydric Soil Indicators (Applicable to all LRRs, unless otherwise noted):

___ Histosol (A1)
___ Histic Epipedon (A2)
___ Black Histic (A3)
___ Hydrogen Sulfide (A4)
X Depleted Below Dark Surface (A11)
___ Thick Dark Surface (A12)
___ Sandy Mucky Mineral (S1)
___ Sandy Gleyed Matrix (S4)
___ Sandy Redox (S5)
___ Stripped Matrix (S6)
___ Loamy Mucky Mineral (F1) (except MLRA 1)
___ Loamy Gleyed Matrix (F2)
X Depleted Matrix (F3)
___ Redox Dark Surface (F6)
___ Depleted Dark Surface (F7)
___ Redox Depressions (F8)

Indicators for Problematic Hydric Soils[3]:

___ 2 cm Muck (A10)
___ Red Parent Material (TF2)
___ Very Shallow Dark Surface (TF12)
___ Other (Explain in Remarks)

[3]Indicators of hydrophytic vegetation and wetland hydrology must be present, unless disturbed or problematic.

Restrictive Layer (if present):

Type: none
Depth (inches): na

Hydric Soil Present? **Yes** X **No** ___

Remarks:

HYDROLOGY

Wetland Hydrology Indicators:

Primary Indicators (minimum of one required; check all that apply)

___ Surface Water (A1)
___ High Water Table (A2)
___ Saturation (A3)
___ Water Marks (B1)
___ Sediment Deposits (B2)
___ Drift Deposits (B3)
___ Algal Mat or Crust (B4)

RATING SUMMARY – Western Washington

Name of wetland (or ID #): WFW-01

Date of site visit: 10/9/2019

Rated by A. Weiss

Trained by Ecology?☑ Yes☐ No

Date of training Oct-20

HGM Class used for rating Depressional & Flats

Wetland has multiple HGM classes?☑ Yes☐ No

NOTE: Form is not complete with out the figures requested (*figures can be combined*).

OVERALL WETLAND CATEGORY III (based on functions☑ or special characteristics ☐)

1. Category of wetland based on FUNCTIONS

___ **Category I** - Total score = 23 - 27

___ **Category II** - Total score = 20 - 22

X **Category III** - Total score = 16 - 19

___ **Category IV** - Total score = 9 - 15

FUNCTION	**Improving Water Quality**	**Hydrologic**	**Habitat**	
	List appropriate rating (H, M, L)			
Site Potential	M	L	M	
Landscape Potential	M	H	L	
Value	M	M	H	**Total**
Score Based on Ratings	6	6	6	**18**

Score for each function based on three ratings (*order of ratings is not important*)

9 = H, H, H
8 = H, H, M
7 = H, H, L
7 = H, M, M
6 = H, M, L
6 = M, M, M
5 = H, L, L
5 = M, M, L
4 = M, L, L
3 = L, L, L

2. Category based on SPECIAL CHARACTERISTICS of wetland

CHARACTERISTIC	**Category**
Estuarine	
Wetland of High Conservation Value	
Bog	
Mature Forest	
Old Growth Forest	
Coastal Lagoon	
Interdunal	
None of the above	X

Maps and Figures required to answer questions correctly for Western Washington

Depressional Wetlands

Map of:	To answer questions:	Figure #
Cowardin plant classes	D 1.3, H 1.1, H 1.4	
Hydroperiods	D 1.4, H 1.2	
Location of outlet (*can be added to map of hydroperiods*)	D 1.1, D 4.1	
Boundary of area within 150 ft of the wetland (*can be added to another figure*)	D 2.2, D 5.2	
Map of the contributing basin	D 4.3, D 5.3	
1 km Polygon: Area that extends 1 km from entire wetland edge - including polygons for accessible habitat and undisturbed habitat	H 2.1, H 2.2, H 2.3	
Screen capture of map of 303(d) listed waters in basin (from Ecology website)	D 3.1, D 3.2	
Screen capture of list of TMDLs for WRIA in which unit is found (from web)	D 3.3	

Riverine Wetlands

Map of:	To answer questions:	Figure #
Cowardin plant classes	H 1.1, H 1.4	
Hydroperiods	H 1.2	
Ponded depressions	R 1.1	
Boundary of area within 150 ft of the wetland (*can be added to another figure*)	R 2.4	
Plant cover of trees, shrubs, and herbaceous plants	R 1.2, R 4.2	
Width of unit vs. width of stream (*can be added to another figure*)	R 4.1	
Map of the contributing basin	R 2.2, R 2.3, R 5.2	
1 km Polygon: Area that extends 1 km from entire wetland edge - including polygons for accessible habitat and undisturbed habitat	H 2.1, H 2.2, H 2.3	
Screen capture of map of 303(d) listed waters in basin (from Ecology website)	R 3.1	
Screen capture of list of TMDLs for WRIA in which unit is found (from web)	R 3.2, R 3.3	

Lake Fringe Wetlands

Map of:	To answer questions:	Figure #
Cowardin plant classes	L 1.1, L 4.1, H 1.1, H 1.4	
Plant cover of trees, shrubs, and herbaceous plants	L 1.2	
Boundary of area within 150 ft of the wetland (*can be added to another figure*)	L 2.2	
1 km Polygon: Area that extends 1 km from entire wetland edge - including polygons for accessible habitat and undisturbed habitat	H 2.1, H 2.2, H 2.3	
Screen capture of map of 303(d) listed waters in basin (from Ecology website)	L 3.1, L 3.2	
Screen capture of list of TMDLs for WRIA in which unit is found (from web)	L 3.3	

Slope Wetlands

Map of:	To answer questions:	Figure #
Cowardin plant classes	H 1.1, H 1.4	
Hydroperiods	H 1.2	
Plant cover of **dense** trees, shrubs, and herbaceous plants	S 1.3	
Plant cover of **dense, rigid** trees, shrubs, and herbaceous plants (*can be added to another figure*)	S 4.1	
Boundary of area within 150 ft of the wetland (*can be added to another figure*)	S 2.1, S 5.1	
1 km Polygon: Area that extends 1 km from entire wetland edge - including polygons for accessible habitat and undisturbed habitat	H 2.1, H 2.2, H 2.3	
Screen capture of map of 303(d) listed waters in basin (from Ecology website)	S 3.1, S 3.2	
Screen capture of list of TMDLs for WRIA in which unit is found (from web)	S 3.3	

HGM Classification of Wetland in Western Washington

For questions 1 -7, the criteria described must apply to the entire unit being rated.
If hydrologic criteria listed in each question do not apply to the entire unit being rated, you probably have a unit with multiple HGM classes. In this case, identify which hydrologic criteria in questions 1 - 7 apply, and go to Question 8.

1. Are the water levels in the entire unit usually controlled by tides except during floods?

☑ NO - go to 2 ☐ **YES** - the wetland class is **Tidal Fringe** - go to 1.1

1.1 Is the salinity of the water during periods of annual low flow below 0.5 ppt (parts per thousand)?

☐ **NO - Saltwater Tidal Fringe (Estuarine)** ☐ **YES - Freshwater Tidal Fringe**
If your wetland can be classified as a Freshwater Tidal Fringe use the forms for ***Riverine*** *wetlands. If it is Saltwater Tidal Fringe it is an* ***Estuarine*** *wetland and is not scored. This method* ***cannot*** *be used to score functions for estuarine wetlands.*

2. The entire wetland unit is flat and precipitation is the only source (>90%) of water to it.
Groundwater and surface water runoff are NOT sources of water to the unit.

☑ NO - go to 3 ☐ **YES** - The wetland class is **Flats**
If your wetland can be classified as a Flats wetland, use the form for ***Depressional*** *wetlands.*

3. Does the entire wetland unit **meet all** of the following criteria?
☐ The vegetated part of the wetland is on the shores of a body of permanent open water (without any plants on the surface at any time of the year) at least 20 ac (8 ha) in size;
☐ At least 30% of the open water area is deeper than 6.6 ft (2 m).

☑ NO - go to 4 ☐ **YES** - The wetland class is **Lake Fringe** (Lacustrine Fringe)

4. Does the entire wetland unit **meet all** of the following criteria?
☐ The wetland is on a slope (*slope can be very gradual*),
☐ The water flows through the wetland in one direction (unidirectional) and usually comes from seeps. It may flow subsurface, as sheetflow, or in a swale without distinct banks.
☐ The water leaves the wetland **without being impounded.**

☑ NO - go to 5 ☐ **YES** - The wetland class is **Slope**

NOTE: Surface water does not pond in these type of wetlands except occasionally in very small and shallow depressions or behind hummocks (depressions are usually <3 ft diameter and less than 1 ft deep).

5. Does the entire wetland unit **meet all** of the following criteria?
☐ The unit is in a valley, or stream channel, where it gets inundated by overbank flooding from that stream or river,
☐ The overbank flooding occurs at least once every 2 years.

☑ NO - go to 6 ☐ **YES** - The wetland class is **Riverine**

NOTE: The Riverine unit can contain depressions that are filled with water when the river is not flooding.

6. Is the entire wetland unit in a topographic depression in which water ponds, or is saturated to the surface, at some time during the year? *This means that any outlet, if present, is higher than the interior of the wetland.*

☐ NO - go to 7 ☑ **YES** - The wetland class is **Depressional**

7. Is the entire wetland unit located in a very flat area with no obvious depression and no overbank flooding? The unit does not pond surface water more than a few inches. The unit seems to be maintained by high groundwater in the area. The wetland may be ditched, but has no obvious natural outlet.

☐ NO - go to 8 ☐ **YES** - The wetland class is **Depressional**

8. Your wetland unit seems to be difficult to classify and probably contains several different HGM classes. For example, seeps at the base of a slope may grade into a riverine floodplain, or a small stream within a Depressional wetland has a zone of flooding along its sides. GO BACK AND IDENTIFY WHICH OF THE HYDROLOGIC REGIMES DESCRIBED IN QUESTIONS 1-7 APPLY TO DIFFERENT AREAS IN THE UNIT (make a rough sketch to help you decide). Use the following table to identify the appropriate class to use for the rating system if you have several HGM classes present within the wetland unit being scored.

NOTE: Use this table only if the class that is recommended in the second column represents 10% or more of the total area of the wetland unit being rated. If the area of the HGM class listed in column 2 is less than 10% of the unit; classify the wetland using the class that represents more than 90% of the total area.

HGM classes within the wetland unit being rated	HGM class to use in rating
Slope + Riverine	Riverine
Slope + Depressional	Depressional
Slope + Lake Fringe	Lake Fringe
Depressional + Riverine along stream within boundary of depression	Depressional
Depressional + Lake Fringe	Depressional
Riverine + Lake Fringe	Riverine
Salt Water Tidal Fringe and any other class of freshwater wetland	Treat as ESTUARINE

If you are still unable to determine which of the above criteria apply to your wetland, or if you have ***more than 2 HGM classes*** *within a wetland boundary, classify the wetland as Depressional for the rating.*

NOTES and FIELD OBSERVATIONS:
A portion of the wetland is riverine and a portion is depressional. Depressional + Riverine along stream within boundary of depression, therefore the HGM class used for this rating is Depressional.

DEPRESSIONAL AND FLATS WETLANDS

Water Quality Functions - Indicators that the site functions to improve water quality

D 1.0. Does the site have the potential to improve water quality?	
D 1.1. Characteristics of surface water outflows from the wetland: Wetland is a depression or flat depression (QUESTION 7 on key) with no surface water leaving it (no outlet). points = 3 Wetland has an intermittently flowing stream or ditch, OR highly constricted permanently flowing outlet. points = 2 ☐ Wetland has an unconstricted, or slightly constricted, surface outlet that is permanently flowing points = 1 ☐ Wetland is a flat depression (QUESTION 7 on key), whose outlet is a permanently flowing ditch. points = 1	2
D 1.2. The soil 2 in below the surface (or duff layer) is true clay or true organic (*use NRCS definitions*). Yes = 4 No = 0	0
D 1.3. Characteristics and distribution of persistent plants (Emergent, Scrub-shrub, and/or Forested Cowardin classes): Wetland has persistent, ungrazed, plants > 95% of area points = 5 Wetland has persistent, ungrazed, plants > ½ of area points = 3 Wetland has persistent, ungrazed plants > $^{1}/_{10}$ of area points = 1 Wetland has persistent, ungrazed plants < $^{1}/_{10}$ of area points = 0	5
D 1.4. Characteristics of seasonal ponding or inundation: *This is the area that is ponded for at least 2 months. See description in manual.* Area seasonally ponded is > ½ total area of wetland points = 4 Area seasonally ponded is > ¼ total area of wetland points = 2 Area seasonally ponded is < ¼ total area of wetland points = 0	4
Total for D 1 Add the points in the boxes above	**11**

Rating of Site Potential If score is: ☐ **12 - 16 = H** ☑ **6 - 11 = M** ☐ **0 - 5 = L** *Record the rating on the first page*

D 2.0. Does the landscape have the potential to support the water quality function of the site?	
D 2.1. Does the wetland unit receive stormwater discharges? Yes = 1 No = 0	1
D 2.2. Is > 10% of the area within 150 ft of the wetland in land uses that generate pollutants? Yes = 1 No = 0	1
D 2.3. Are there septic systems within 250 ft of the wetland? Yes = 1 No = 0	0
D 2.4. Are there other sources of pollutants coming into the wetland that are not listed in questions D 2.1 - D 2.3? Source Yes = 1 No = 0	0
Total for D 2 Add the points in the boxes above	**2**

Rating of Landscape Potential If score is:☐ **3 or 4 = H** ☑ **1 or 2 = M** ☐ **0 = L** *Record the rating on the first page*

D 3.0. Is the water quality improvement provided by the site valuable to society?	
D 3.1. Does the wetland discharge directly (i.e., within 1 mi) to a stream, river, lake, or marine water that is on the 303(d) list? Yes = 1 No = 0	0
D 3.2. Is the wetland in a basin or sub-basin where an aquatic resource is on the 303(d) list? Yes = 1 No = 0	1
D 3.3. Has the site been identified in a watershed or local plan as important for maintaining water quality (*answer YES if there is a TMDL for the basin in which the unit is found*)? Yes = 2 No = 0	0
Total for D 3 Add the points in the boxes above	**1**

Rating of Value If score is:☐ **2 - 4 = H** ☑ **1 = M** ☐ **0 = L** *Record the rating on the first page*

Wetland name or number WFW-01

DEPRESSIONAL AND FLATS WETLANDS

Hydrologic Functions - Indicators that the site functions to reduce flooding and stream degradation

D 4.0. Does the site have the potential to reduce flooding and erosion?		
D 4.1. Characteristics of surface water outflows from the wetland: Wetland is a depression or flat depression with no surface water leaving it (no outlet) Wetland has an intermittently flowing stream or ditch, OR highly constricted permanently flowing outlet Wetland is a flat depression (QUESTION 7 on key), whose outlet is a permanently flowing ditch Wetland has an unconstricted, or slightly constricted, surface outlet that is permanently flowing	 points = 4 points = 2 points = 1 points = 0	2
D 4.2. Depth of storage during wet periods: *Estimate the height of ponding above the bottom of the outlet. For wetlands with no outlet, measure from the surface of permanent water or if dry, the deepest part.* Marks of ponding are 3 ft or more above the surface or bottom of outlet Marks of ponding between 2 ft to < 3 ft from surface or bottom of outlet ☑ Marks are at least 0.5 ft to < 2 ft from surface or bottom of outlet ☐ The wetland is a “headwater” wetland Wetland is flat but has small depressions on the surface that trap water Marks of ponding less than 0.5 ft (6 in)	 points = 7 points = 5 points = 3 points = 3 points = 1 points = 0	3
D 4.3. Contribution of the wetland to storage in the watershed: *Estimate the ratio of the area of upstream basin contributing surface water to the wetland to the area of the wetland unit itself.* ☐ The area of the basin is less than 10 times the area of the unit The area of the basin is 10 to 100 times the area of the unit The area of the basin is more than 100 times the area of the unit ☐ Entire wetland is in the Flats class	 points = 5 points = 3 points = 0 points = 5	0
Total for D 4	Add the points in the boxes above	**5**

Rating of Site Potential If score is: ☐ **12 - 16 = H** ☐ **6 - 11 = M** ☑ **0 - 5 = L** *Record the rating on the first page*

D 5.0. Does the landscape have the potential to support hydrologic function of the site?		
D 5.1. Does the wetland unit receive stormwater discharges?	Yes = 1 No = 0	1
D 5.2. Is > 10% of the area within 150 ft of the wetland in land uses that generate excess runoff?	Yes = 1 No = 0	1
D 5.3. Is more than 25% of the contributing basin of the wetland covered with intensive human land uses (residential at >1 residence/ac, urban, commercial, agriculture, etc.)?	Yes = 1 No = 0	1
Total for D 5	Add the points in the boxes above	**3**

Rating of Landscape Potential If score is: ☑ **3 = H** ☐ **1 or 2 = M** ☐ **0 = L** *Record the rating on the first page*

D 6.0. Are the hydrologic functions provided by the site valuable to society?		
D 6.1. The unit is in a landscape that has flooding problems. *Choose the description that best matches conditions around the wetland unit being rated. Do not add points. Choose the highest score if more than one condition is met.* The wetland captures surface water that would otherwise flow down-gradient into areas where flooding has damaged human or natural resources (e.g., houses or salmon redds): • Flooding occurs in a sub-basin that is immediately down-gradient of unit. ☑ • Surface flooding problems are in a sub-basin farther down-gradient. ☐ Flooding from groundwater is an issue in the sub-basin. ☐ The existing or potential outflow from the wetland is so constrained by human or natural conditions that the water stored by the wetland cannot reach areas that flood. Explain why ☐ There are no problems with flooding downstream of the wetland.	 points = 2 points = 1 points = 1 points = 0 points = 0	1
D 6.2. Has the site been identified as important for flood storage or flood conveyance in a regional flood control plan?	Yes = 2 No = 0	0
Total for D 6	Add the points in the boxes above	**1**

Rating of Value If score is: ☐ **2 - 4 = H** ☑ **1 = M** ☐ **0 = L** *Record the rating on the first page*

These questions apply to wetlands of all HGM classes.

HABITAT FUNCTIONS - Indicators that site functions to provide important habitat

H 1.0. Does the site have the potential to provide habitat?

H 1.1. Structure of plant community: *Indicators are Cowardin classes and strata within the Forested class.* Check the Cowardin plant classes in the wetland. *Up to 10 patches may be combined for each class to meet the threshold of ¼ ac or more than 10% of the unit if it is smaller than 2.5 ac. Add the number of structures checked.*

☐ Aquatic bed
☐ Emergent
☐ Scrub-shrub (areas where shrubs have > 30% cover)
☑ Forested (areas where trees have > 30% cover)

4 structures or more: points = 4
3 structures: points = 2
2 structures: points - 1
1 structure: points = 0

If the unit has a Forested class, check if :

☑ The Forested class has 3 out of 5 strata (canopy, sub-canopy, shrubs, herbaceous, moss/ground-cover) that each cover 20% within the Forested polygon

1

H 1.2. Hydroperiods

Check the types of water regimes (hydroperiods) present within the wetland. The water regime has to cover more than 10% of the wetland or ¼ ac to count (*see text for descriptions of hydroperiods*).

☐ Permanently flooded or inundated
☑ Seasonally flooded or inundated
☑ Occasionally flooded or inundated
☑ Saturated only
☐ Permanently flowing stream or river in, or adjacent to, the wetland
☑ Seasonally flowing stream in, or adjacent to, the wetland
☐ **Lake Fringe wetland** **2 points**
☐ **Freshwater tidal wetland** **2 points**

4 or more types present: points = 3
3 types present: points = 2
2 types present: points = 1
1 types present: points = 0

3

H 1.3. Richness of plant species

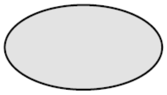
Count the number of plant species in the wetland that cover at least 10 ft^2.
Different patches of the same species can be combined to meet the size threshold and you do not have to name the species. ***Do not include Eurasian milfoil, reed canarygrass, purple loosestrife, Canadian thistle***

If you counted:
> 19 species points = 2
5 - 19 species points = 1
< 5 species points = 0

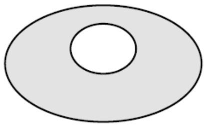
1

H 1.4. Interspersion of habitats

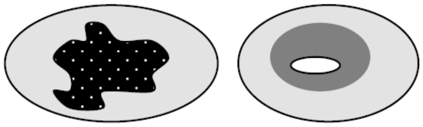
Decide from the diagrams below whether interspersion among Cowardin plants classes (described in H 1.1), or the classes and unvegetated areas (can include open water or mudflats) is high, moderate, low, or none. *If you have four or more plant classes or three classes and open water, the rating is always high.*



None = 0 points

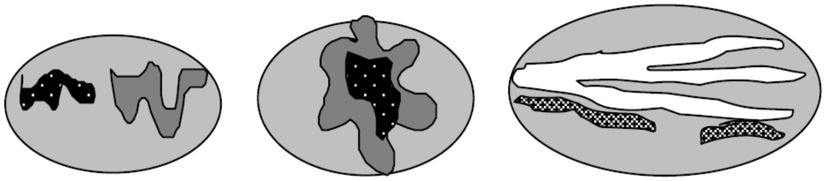


Low = 1 point



Moderate = 2 points

All three diagrams in this row are **HIGH** = 3 points



1

H 1.5. Special habitat features: Check the habitat features that are present in the wetland. *The number of checks is the number of points.* ☑ Large, downed, woody debris within the wetland (> 4 in diameter and 6 ft long) ☑ Standing snags (dbh > 4 in) within the wetland ☑ Undercut banks are present for at least 6.6 ft (2 m) **and/or** overhanging plants extends at least 3.3 ft (1 m) over a stream (or ditch) in, or contiguous with the wetland, for at least 33 ft (10 m) ☐ Stable steep banks of fine material that might be used by beaver or muskrat for denning (> 30 degree slope) OR signs of recent beaver activity are present (*cut shrubs or trees that have not yet weathered where wood is exposed*) ☐ At least ¼ ac of thin-stemmed persistent plants or woody branches are present in areas that are permanently or seasonally inundated (*structures for egg-laying by amphibians*) ☐ Invasive plants cover less than 25% of the wetland area in every stratum of plants (*see H 1.1 for list of strata*)	3
Total for H 1 — Add the points in the boxes above	**9**

Rating of Site Potential If Score is: ☐ **15 - 18 = H** ☑ **7 - 14 = M** ☐ **0 - 6 = L** *Record the rating on the first page*

H 2.0. Does the landscape have the potential to support the habitat function of the site?	
H 2.1 Accessible habitat (include *only habitat that directly abuts wetland unit*). *Calculate:* 2.4 % undisturbed habitat + (1.2 % moderate & low intensity land uses / 2) = 3% If total accessible habitat is: > $^1/_3$ (33.3%) of 1 km Polygon — points = 3 20 - 33% of 1 km Polygon — points = 2 10 - 19% of 1 km Polygon — points = 1 < 10 % of 1 km Polygon — points = 0	0
H 2.2. Undisturbed habitat in 1 km Polygon around the wetland. *Calculate:* 25.2 % undisturbed habitat + (22.2 % moderate & low intensity land uses / 2) = 36.3% Undisturbed habitat > 50% of Polygon — points = 3 Undisturbed habitat 10 - 50% and in 1-3 patches — points = 2 Undisturbed habitat 10 - 50% and > 3 patches — points = 1 Undisturbed habitat < 10% of 1 km Polygon — points = 0	1
H 2.3 Land use intensity in 1 km Polygon: If > 50% of 1 km Polygon is high intensity land use — points = (-2) ≤ 50% of 1km Polygon is high intensity — points = 0	-2
Total for H 2 — Add the points in the boxes above	**-1**

Rating of Landscape Potential If Score is: ☐ **4 - 6 = H** ☐ **1 - 3 = M** ☑ **< 1 = L** *Record the rating on the first page*

H 3.0. Is the habitat provided by the site valuable to society?	
H 3.1. Does the site provide habitat for species valued in laws, regulations, or policies? *Choose only the highest score that applies to the wetland being rated*. Site meets ANY of the following criteria: — points = 2 ☑ It has 3 or more priority habitats within 100 m (see next page) ☐ It provides habitat for Threatened or Endangered species (any plant or animal on the state or federal lists) ☐ It is mapped as a location for an individual WDFW priority species ☐ It is a Wetland of High Conservation Value as determined by the Department of Natural Resources ☐ It has been categorized as an important habitat site in a local or regional comprehensive plan, in a Shoreline Master Plan, or in a watershed plan Site has 1 or 2 priority habitats (listed on next page) with in 100m — points = 1 Site does not meet any of the criteria above — points = 0	2

Rating of Value If Score is: ☑ **2 = H** ☐ **1 = M** ☐ **0 = L** *Record the rating on the first page*

WDFW Priority Habitats

Priority habitats listed by WDFW (see complete descriptions of WDFW priority habitats, and the counties in which they can be found, in: Washington Department of Fish and Wildlife. 2008. Priority Habitat and Species List. Olympia, Washington. 177 pp.
http://wdfw.wa.gov/publications/00165/wdfw00165.pdf or access the list from here:
http://wdfw.wa.gov/conservation/phs/list/

Count how many of the following priority habitats are within 330 ft (100 m) of the wetland unit: ***NOTE**: This question is independent of the land use between the wetland unit and the priority habitat.*

- ☐ **Aspen Stands**: Pure or mixed stands of aspen greater than 1 ac (0.4 ha).
- ☐ **Biodiversity Areas and Corridors**: Areas of habitat that are relatively important to various species of native fish and wildlife (*full descriptions in WDFW PHS report*).
- ☐ **Herbaceous Balds**: Variable size patches of grass and forbs on shallow soils over bedrock.
- ☑ **Old-growth/Mature forests**: Old-growth west of Cascade crest – Stands of at least 2 tree species, forming a multi-layered canopy with occasional small openings; with at least 8 trees/ac (20 trees/ha) > 32 in (81 cm) dbh or > 200 years of age. Mature forests – Stands with average diameters exceeding 21 in (53 cm) dbh; crown cover may be less than 100%; decay, decadence, numbers of snags, and quantity of large downed material is generally less than that found in old-growth; 80-200 years old west of the Cascade crest.
- ☐ **Oregon White Oak**: Woodland stands of pure oak or oak/conifer associations where canopy coverage of the oak component is important (*full descriptions in WDFW PHS report p. 158 – see web link above*).
- ☑ **Riparian**: The area adjacent to aquatic systems with flowing water that contains elements of both aquatic and terrestrial ecosystems which mutually influence each other.
- ☐ **Westside Prairies**: Herbaceous, non-forested plant communities that can either take the form of a dry prairie or a wet prairie (*full descriptions in WDFW PHS report p. 161 – see web link above*).
- ☑ **Instream**: The combination of physical, biological, and chemical processes and conditions that interact to provide functional life history requirements for instream fish and wildlife resources.
- ☐ **Nearshore**: Relatively undisturbed nearshore habitats. These include Coastal Nearshore, Open Coast Nearshore, and Puget Sound Nearshore. (*full descriptions of habitats and the definition of relatively undisturbed are in WDFW report – see web link on previous page*).
- ☐ **Caves**: A naturally occurring cavity, recess, void, or system of interconnected passages under the earth in soils, rock, ice, or other geological formations and is large enough to contain a human.
- ☐ **Cliffs**: Greater than 25 ft (7.6 m) high and occurring below 5000 ft elevation.
- ☐ **Talus**: Homogenous areas of rock rubble ranging in average size 0.5 - 6.5 ft (0.15 - 2.0 m), composed of basalt, andesite, and/or sedimentary rock, including riprap slides and mine tailings. May be associated with cliffs.
- ☑ **Snags and Logs**: Trees are considered snags if they are dead or dying and exhibit sufficient decay characteristics to enable cavity excavation/use by wildlife. Priority snags have a diameter at breast height of > 20 in (51 cm) in western Washington and are > 6.5 ft (2 m) in height. Priority logs are > 12 in (30 cm) in diameter at the largest end, and > 20 ft (6 m) long.

Note: All vegetated wetlands are by definition a priority habitat but are not included in this list because they are addressed elsewhere.

Wetland name or number __WFW-01____

CATEGORIZATION BASED ON SPECIAL CHARACTERISTICS

Wetland Type *Check off any criteria that apply to the wetland. List the category when the appropriate criteria are met.*	**Category**

SC 1.0. Estuarine Wetlands

Does the wetland meet the following criteria for Estuarine wetlands?

☐ The dominant water regime is tidal,
☐ Vegetated, and
☐ With a salinity greater than 0.5 ppt

☐ Yes - Go to **SC 1.1** ☑ No = **Not an estuarine wetland**

SC 1.1. Is the wetland within a National Wildlife Refuge, National Park, National Estuary Reserve, Natural Area Preserve, State Park or Educational, Environmental, or Scientific Reserve designated under WAC 332-30-151?

☐ Yes = **Category I** ☐ No - Go to **SC 1.2**

SC 1.2. Is the wetland unit at least 1 ac in size and meets at least two of the following three conditions?

☐ The wetland is relatively undisturbed (has no diking, ditching, filling, cultivation, grazing, and has less than 10% cover of non-native plant species. (If non-native species are *Spartina*, see page 25)
☐ At least ¾ of the landward edge of the wetland has a 100 ft buffer of shrub, forest, or un-grazed or un-mowed grassland.
☐ The wetland has at least two of the following features: tidal channels, depressions with open water, or contiguous freshwater wetlands.

☐ Yes = **Category I** ☐ No = **Category II**

SC 2.0. Wetlands of High Conservation Value (WHCV)

SC 2.1. Has the WA Department of Natural Resources updated their website to include the list of Wetlands of High Conservation Value?

☑ Yes - Go to **SC 2.2** ☐ No - Go to **SC 2.3**

SC 2.2. Is the wetland listed on the WDNR database as a Wetland of High Conservation Value?

☐ Yes = **Category I** ☑ No = **Not WHCV**

SC 2.3. Is the wetland in a Section/Township/Range that contains a Natural Heritage wetland?
http://www1.dnr.wa.gov/nhp/refdesk/datasearch/wnhpwetlands.pdf

☐ Yes - **Contact WNHP/WDNR and to SC 2.4** ☐ No = **Not WHCV**

SC 2.4. Has WDNR identified the wetland within the S/T/R as a Wetland of High Conservation Value and listed it on their website?

☐ Yes = **Category I** ☐ No = **Not WHCV**

SC 3.0. Bogs

Does the wetland (or any part of the unit) meet both the criteria for soils and vegetation in bogs? *Use the key below.* ***If you answer YES you will still need to rate the wetland based on its functions***.

SC 3.1. Does an area within the wetland unit have organic soil horizons, either peats or mucks, that compose 16 in or more of the first 32 in of the soil profile?

☐ Yes - Go to **SC 3.3** ☑ No - Go to **SC 3.2**

SC 3.2. Does an area within the wetland unit have organic soils, either peats or mucks, that are less than 16 in deep over bedrock, or an impermeable hardpan such as clay or volcanic ash, or that are floating on top of a lake or pond?

☐ Yes - Go to **SC 3.3** ☑ No = **Is not a bog**

SC 3.3. Does an area with peats or mucks have more than 70% cover of mosses at ground level, AND at least a 30% cover of plant species listed in Table 4?

☐ Yes = **Is a Category I bog** ☐ No - Go to **SC 3.4**

NOTE: If you are uncertain about the extent of mosses in the understory, you may substitute that criterion by measuring the pH of the water that seeps into a hole dug at least 16 in deep. If the pH is less than 5.0 and the plant species in Table 4 are present, the wetland is a bog.

SC 3.4. Is an area with peats or mucks forested (> 30% cover) with Sitka spruce, subalpine fir, western red cedar, western hemlock, lodgepole pine, quaking aspen, Engelmann spruce, or western white pine, AND any of the species (or combination of species) listed in Table 4 provide more than 30% of the cover under the canopy?

☐ Yes = **Is a Category I bog** ☐ No = **Is not a bog**

SC 4.0. Forested Wetlands

Does the wetland have at least 1 contiguous acre of forest that meets one of these criteria for the WA Department of Fish and Wildlife's forests as priority habitats? ***If you answer YES you will still need to rate the wetland based on its functions.***

☐ **Old-growth forests** (west of Cascade crest): Stands of at least two tree species, forming a multi-layered canopy with occasional small openings; with at least 8 trees/ac (20 trees/ha) that are at least 200 years of age OR have a diameter at breast height (dbh) of 32 in (81 cm) or more.

☐ **Mature forests** (west of the Cascade Crest): Stands where the largest trees are 80- 200 years old OR the species that make up the canopy have an average diameter (dbh) exceeding 21 in (53 cm).

☐ Yes = **Category I** ☑ No = **Not a forested wetland for this section**

SC 5.0. Wetlands in Coastal Lagoons

Does the wetland meet all of the following criteria of a wetland in a coastal lagoon?

☐ The wetland lies in a depression adjacent to marine waters that is wholly or partially separated from marine waters by sandbanks, gravel banks, shingle, or, less frequently, rocks

☐ The lagoon in which the wetland is located contains ponded water that is saline or brackish (> 0.5 ppt) during most of the year in at least a portion of the lagoon (*needs to be measured near the bottom*)

☐ Yes - Go to **SC 5.1** ☑ No = **Not a wetland in a coastal lagoon**

SC 5.1. Does the wetland meet all of the following three conditions?

☐ The wetland is relatively undisturbed (has no diking, ditching, filling, cultivation, grazing), and has less than 20% cover of aggressive, opportunistic plant species (see list of species on p. 100).

☐ At least ¾ of the landward edge of the wetland has a 100 ft buffer of shrub, forest, or un-grazed or un-mowed grassland.

☐ The wetland is larger than $^{1}/_{10}$ ac (4350 ft^2)

☐ Yes = **Category I** ☐ No = **Category II**

SC 6.0. Interdunal Wetlands

Is the wetland west of the 1889 line (also called the Western Boundary of Upland Ownership or WBUO)? ***If you answer yes you will still need to rate the wetland based on its habitat functions.***

In practical terms that means the following geographic areas:

☐ Long Beach Peninsula: Lands west of SR 103

☐ Grayland-Westport: Lands west of SR 105

☐ Ocean Shores-Copalis: Lands west of SR 115 and SR 109

☐ Yes - Go to **SC 6.1** ☑ No = **Not an interdunal wetland for rating**

SC 6.1. Is the wetland 1 ac or larger and scores an 8 or 9 for the habitat functions on the form (rates H,H,H or H,H,M for the three aspects of function)?

☐ Yes = **Category I** ☐ No - Go to **SC 6.2**

SC 6.2. Is the wetland 1 ac or larger, or is it in a mosaic of wetlands that is 1 ac or larger?

☐ Yes = **Category II** ☐ No - Go to **SC 6.3**

SC 6.3. Is the unit between 0.1 and 1 ac, or is it in a mosaic of wetlands that is between 0.1 and 1 ac?

☐ Yes = **Category III** ☐ No = **Category IV**

Category of wetland based on Special Characteristics

If you answered No for all types, enter "Not Applicable" on Summary Form

RATING SUMMARY – Western Washington

Name of wetland (or ID #): WFW-02 Date of site visit: 10/16/2019

Rated by A. Weiss Trained by Ecology? ☑ Yes ☐ No Date of training Oct-20

HGM Class used for rating Depressional & Flats Wetland has multiple HGM classes? ☑ Yes ☐ No

NOTE: Form is not complete with out the figures requested (*figures can be combined*).

Interdunal	
None of the above	**X**

Maps and Figures required to answer questions correctly for Western Washington

Depressional Wetlands

Map of:	To answer questions:	Figure #
Cowardin plant classes	D 1.3, H 1.1, H 1.4	
Hydroperiods	D 1.4, H 1.2	
Location of outlet (*can be added to map of hydroperiods*)	D 1.1, D 4.1	
Boundary of area within 150 ft of the wetland (*can be added to another figure*)	D 2.2, D 5.2	
Map of the contributing basin	D 4.3, D 5.3	
1 km Polygon: Area that extends 1 km from entire wetland edge - including polygons for accessible habitat and undisturbed habitat	H 2.1, H 2.2, H 2.3	
Screen capture of map of 303(d) listed waters in basin (from Ecology website)	D 3.1, D 3.2	
Screen capture of list of TMDLs for WRIA in which unit is found (from web)	D 3.3	

Riverine Wetlands

Map of:	To answer questions:	Figure #
Cowardin plant classes	H 1.1, H 1.4	
Hydroperiods	H 1.2	
Ponded depressions	R 1.1	
Boundary of area within 150 ft of the wetland (*can be added to another figure*)	R 2.4	
Plant cover of trees, shrubs, and herbaceous plants	R 1.2, R 4.2	
Width of unit vs. width of stream (*can be added to another figure*)	R 4.1	
Map of the contributing basin	R 2.2, R 2.3, R 5.2	
1 km Polygon: Area that extends 1 km from entire wetland edge - including polygons for accessible habitat and undisturbed habitat	H 2.1, H 2.2, H 2.3	
Screen capture of map of 303(d) listed waters in basin (from Ecology website)	R 3.1	
Screen capture of list of TMDLs for WRIA in which unit is found (from web)	R 3.2, R 3.3	

Lake Fringe Wetlands

Map of:	To answer questions:	Figure #
Cowardin plant classes	L 1.1, L 4.1, H 1.1, H 1.4	
Plant cover of trees, shrubs, and herbaceous plants	L 1.2	
Boundary of area within 150 ft of the wetland (*can be added to another figure*)	L 2.2	
1 km Polygon: Area that extends 1 km from entire wetland edge - including polygons for accessible habitat and undisturbed habitat	H 2.1, H 2.2, H 2.3	
Screen capture of map of 303(d) listed waters in basin (from Ecology website)	L 3.1, L 3.2	
Screen capture of list of TMDLs for WRIA in which unit is found (from web)	L 3.3	

Slope Wetlands

Map of:	To answer questions:	Figure #
Cowardin plant classes	H 1.1, H 1.4	
Hydroperiods	H 1.2	
Plant cover of **dense** trees, shrubs, and herbaceous plants	S 1.3	
Plant cover of **dense, rigid** trees, shrubs, and herbaceous plants (*can be added to another figure*)	S 4.1	
Boundary of area within 150 ft of the wetland (*can be added to another figure*)	S 2.1, S 5.1	
1 km Polygon: Area that extends 1 km from entire wetland edge - including polygons for accessible habitat and undisturbed habitat	H 2.1, H 2.2, H 2.3	
Screen capture of map of 303(d) listed waters in basin (from Ecology website)	S 3.1, S 3.2	
Screen capture of list of TMDLs for WRIA in which unit is found (from web)	S 3.3	

HGM Classification of Wetland in Western Washington

For questions 1 -7, the criteria described must apply to the entire unit being rated.
If hydrologic criteria listed in each question do not apply to the entire unit being rated, you probably have a unit with multiple HGM classes. In this case, identify which hydrologic criteria in questions 1 - 7 apply, and go to Question 8.

1. Are the water levels in the entire unit usually controlled by tides except during floods?

☑ NO - go to 2 ☐ **YES** - the wetland class is **Tidal Fringe** - go to 1.1

1.1 Is the salinity of the water during periods of annual low flow below 0.5 ppt (parts per thousand)?

☐ **NO - Saltwater Tidal Fringe (Estuarine)** ☐ **YES - Freshwater Tidal Fringe**
If your wetland can be classified as a Freshwater Tidal Fringe use the forms for ***Riverine*** *wetlands. If it is Saltwater Tidal Fringe it is an* ***Estuarine*** *wetland and is not scored. This method* ***cannot*** *be used to score functions for estuarine wetlands.*

2. The entire wetland unit is flat and precipitation is the only source (>90%) of water to it. Groundwater and surface water runoff are NOT sources of water to the unit.

☑ NO - go to 3 ☐ **YES** - The wetland class is **Flats**
If your wetland can be classified as a Flats wetland, use the form for ***Depressional*** *wetlands.*

3. Does the entire wetland unit **meet all** of the following criteria?
☐ The vegetated part of the wetland is on the shores of a body of permanent open water (without any plants on the surface at any time of the year) at least 20 ac (8 ha) in size;
☐ At least 30% of the open water area is deeper than 6.6 ft (2 m).

☑ NO - go to 4 ☐ **YES** - The wetland class is **Lake Fringe** (Lacustrine Fringe)

4. Does the entire wetland unit **meet all** of the following criteria?
☐ The wetland is on a slope (*slope can be very gradual*),
☐ The water flows through the wetland in one direction (unidirectional) and usually comes from seeps. It may flow subsurface, as sheetflow, or in a swale without distinct banks.
☐ The water leaves the wetland **without being impounded.**

☑ NO - go to 5 ☐ **YES** - The wetland class is **Slope**

NOTE: Surface water does not pond in these type of wetlands except occasionally in very small and shallow depressions or behind hummocks (depressions are usually <3 ft diameter and less than 1 ft deep).

5. Does the entire wetland unit **meet all** of the following criteria?
☐ The unit is in a valley, or stream channel, where it gets inundated by overbank flooding from that stream or river,
☐ The overbank flooding occurs at least once every 2 years.

☐ NO - go to 6 ☑ **YES** - The wetland class is **Riverine**

NOTE: The Riverine unit can contain depressions that are filled with water when the river is not flooding.

6. Is the entire wetland unit in a topographic depression in which water ponds, or is saturated to the surface, at some time during the year? *This means that any outlet, if present, is higher than the interior of the*

☐ NO - go to 7 ☑ **YES** - The wetland class is **Depressional**

7. Is the entire wetland unit located in a very flat area with no obvious depression and no overbank flooding? The unit does not pond surface water more than a few inches. The unit seems to be maintained by high groundwater in the area. The wetland may be ditched, but has no obvious natural outlet.

☐ NO - go to 8 ☐ **YES** - The wetland class is **Depressional**

8. Your wetland unit seems to be difficult to classify and probably contains several different HGM classes. For example, seeps at the base of a slope may grade into a riverine floodplain, or a small stream within a Depressional wetland has a zone of flooding along its sides. GO BACK AND IDENTIFY WHICH OF THE HYDROLOGIC REGIMES DESCRIBED IN QUESTIONS 1-7 APPLY TO DIFFERENT AREAS IN THE UNIT (make a rough sketch to help you decide). Use the following table to identify the appropriate class to use for the rating system if you have several HGM classes present within the wetland unit being scored.

NOTE: Use this table only if the class that is recommended in the second column represents 10% or more of the total area of the wetland unit being rated. If the area of the HGM class listed in column 2 is less than 10% of the unit; classify the wetland using the class that represents more than 90% of the total area.

HGM classes within the wetland unit being rated	HGM class to use in rating
Slope + Riverine	Riverine
Slope + Depressional	Depressional
Slope + Lake Fringe	Lake Fringe
Depressional + Riverine along stream within boundary of depression	Depressional
Depressional + Lake Fringe	Depressional
Riverine + Lake Fringe	Riverine
Salt Water Tidal Fringe and any other class of freshwater wetland	Treat as ESTUARINE

If you are still unable to determine which of the above criteria apply to your wetland, or if you have ***more than 2 HGM classes*** *within a wetland boundary, classify the wetland as Depressional for the rating.*

NOTES and FIELD OBSERVATIONS:
A portion of the wetland is riverine and a portion is depressional. Depressional + Riverine along stream within boundary of depression, therefore the HGM class used for this rating is Depressional.

DEPRESSIONAL AND FLATS WETLANDS

Water Quality Functions - Indicators that the site functions to improve water quality

D 1.0. Does the site have the potential to improve water quality?	
D 1.1. Characteristics of surface water outflows from the wetland: Wetland is a depression or flat depression (QUESTION 7 on key) with no surface water leaving it (no outlet). points = 3 Wetland has an intermittently flowing stream or ditch, OR highly constricted permanently flowing outlet. points = 2 ☐ Wetland has an unconstricted, or slightly constricted, surface outlet that is permanently flowing points = 1 ☐ Wetland is a flat depression (QUESTION 7 on key), whose outlet is a permanently flowing ditch. points = 1	2
D 1.2. The soil 2 in below the surface (or duff layer) is true clay or true organic (*use NRCS definitions*). Yes = 4 No = 0	4
D 1.3. Characteristics and distribution of persistent plants (Emergent, Scrub-shrub, and/or Forested Cowardin classes): Wetland has persistent, ungrazed, plants > 95% of area points = 5 Wetland has persistent, ungrazed, plants > ½ of area points = 3 Wetland has persistent, ungrazed plants > $^1/_{10}$ of area points = 1 Wetland has persistent, ungrazed plants < $^1/_{10}$ of area points = 0	5
D 1.4. Characteristics of seasonal ponding or inundation: *This is the area that is ponded for at least 2 months. See description in manual.* Area seasonally ponded is > ½ total area of wetland points = 4 Area seasonally ponded is > ¼ total area of wetland points = 2 Area seasonally ponded is < ¼ total area of wetland points = 0	4
Total for D 1 Add the points in the boxes above	**15**

Rating of Site Potential If score is: ☑ **12 - 16 = H** ☐ **6 - 11 = M** ☐ **0 - 5 = L** *Record the rating on the first page*

D 2.0. Does the landscape have the potential to support the water quality function of the site?	
D 2.1. Does the wetland unit receive stormwater discharges? Yes = 1 No = 0	1
D 2.2. Is > 10% of the area within 150 ft of the wetland in land uses that generate pollutants? Yes = 1 No = 0	1
D 2.3. Are there septic systems within 250 ft of the wetland? Yes = 1 No = 0	0
D 2.4. Are there other sources of pollutants coming into the wetland that are not listed in questions D 2.1 - D 2.3? Source trash Yes = 1 No = 0	1
Total for D 2 Add the points in the boxes above	**3**

Rating of Landscape Potential If score is: ☑ **3 or 4 = H** ☐ **1 or 2 = M** ☐ **0 = L** *Record the rating on the first page*

D 3.0. Is the water quality improvement provided by the site valuable to society?	
D 3.1. Does the wetland discharge directly (i.e., within 1 mi) to a stream, river, lake, or marine water that is on the 303(d) list? Yes = 1 No = 0	1
D 3.2. Is the wetland in a basin or sub-basin where an aquatic resource is on the 303(d) list? Yes = 1 No = 0	1
D 3.3. Has the site been identified in a watershed or local plan as important for maintaining water quality (*answer YES if there is a TMDL for the basin in which the unit is found*)? Yes = 2 No = 0	0
Total for D 3 Add the points in the boxes above	**2**

Rating of Value If score is: ☑ **2 - 4 = H** ☐ **1 = M** ☐ **0 = L** *Record the rating on the first page*

DEPRESSIONAL AND FLATS WETLANDS

Hydrologic Functions - Indicators that the site functions to reduce flooding and stream degradation

D 4.0. Does the site have the potential to reduce flooding and erosion?	
D 4.1. Characteristics of surface water outflows from the wetland: Wetland is a depression or flat depression with no surface water leaving it (no outlet) points = 4 Wetland has an intermittently flowing stream or ditch, OR highly constricted permanently flowing outlet points = 2 Wetland is a flat depression (QUESTION 7 on key), whose outlet is a permanently flowing ditch points = 1 Wetland has an unconstricted, or slightly constricted, surface outlet that is permanently flowing points = 0	2
D 4.2. Depth of storage during wet periods: *Estimate the height of ponding above the bottom of the outlet. For wetlands with no outlet, measure from the surface of permanent water or if dry, the deepest part.* Marks of ponding are 3 ft or more above the surface or bottom of outlet points = 7 Marks of ponding between 2 ft to < 3 ft from surface or bottom of outlet points = 5 ☐ Marks are at least 0.5 ft to < 2 ft from surface or bottom of outlet points = 3 ☐ The wetland is a “headwater” wetland points = 3 Wetland is flat but has small depressions on the surface that trap water points = 1 Marks of ponding less than 0.5 ft (6 in) points = 0	5
D 4.3. Contribution of the wetland to storage in the watershed: *Estimate the ratio of the area of upstream basin contributing surface water to the wetland to the area of the wetland unit itself.* ☐ The area of the basin is less than 10 times the area of the unit points = 5 The area of the basin is 10 to 100 times the area of the unit points = 3 The area of the basin is more than 100 times the area of the unit points = 0 ☐ Entire wetland is in the Flats class points = 5	0
Total for D 4 Add the points in the boxes above	**7**

Rating of Site Potential If score is: ☐ **12 - 16 = H** ☑ **6 - 11 = M** ☐ **0 - 5 = L** *Record the rating on the first page*

D 5.0. Does the landscape have the potential to support hydrologic function of the site?	
D 5.1. Does the wetland unit receive stormwater discharges? Yes = 1 No = 0	1
D 5.2. Is > 10% of the area within 150 ft of the wetland in land uses that generate excess runoff? Yes = 1 No = 0	1
D 5.3. Is more than 25% of the contributing basin of the wetland covered with intensive human land uses (residential at >1 residence/ac, urban, commercial, agriculture, etc.)? Yes = 1 No = 0	1
Total for D 5 Add the points in the boxes above	**3**

Rating of Landscape Potential If score is: ☑ **3 = H** ☐ **1 or 2 = M** ☐ **0 = L** *Record the rating on the first page*

D 6.0. Are the hydrologic functions provided by the site valuable to society?	
D 6.1. The unit is in a landscape that has flooding problems. *Choose the description that best matches conditions around the wetland unit being rated. Do not add points. Choose the highest score if more than one condition is met.* The wetland captures surface water that would otherwise flow down-gradient into areas where flooding has damaged human or natural resources (e.g., houses or salmon ● Flooding occurs in a sub-basin that is immediately down-gradient of unit. points = 2 ☑ ● Surface flooding problems are in a sub-basin farther down-gradient. points = 1 ☐ Flooding from groundwater is an issue in the sub-basin. points = 1 ☐ The existing or potential outflow from the wetland is so constrained by human or natural conditions that the water stored by the wetland cannot reach areas that flood. Explain why points = 0 ☐ There are no problems with flooding downstream of the wetland. points = 0	1
D 6.2. Has the site been identified as important for flood storage or flood conveyance in a regional flood control plan? Yes = 2 No = 0	0
Total for D 6 Add the points in the boxes above	**1**

Rating of Value If score is: ☐ **2 - 4 = H** ☑ **1 = M** ☐ **0 = L** *Record the rating on the first page*

These questions apply to wetlands of all HGM classes.

HABITAT FUNCTIONS - Indicators that site functions to provide important habitat

H 1.0. Does the site have the potential to provide habitat?

H 1.1. Structure of plant community: *Indicators are Cowardin classes and strata within the Forested class.* Check the Cowardin plant classes in the wetland. *Up to 10 patches may be combined for each class to meet the threshold of ¼ ac or more than 10% of the unit if it is smaller than 2.5 ac. Add the number of structures checked.*

☐ Aachat bed — 4 structures or more: points = 4
☐ Emergent — 3 structures: points = 2
☐ Scrub-shrub (areas where shrubs have > 30% cover) — 2 structures: points - 1
☑ Forested (areas where trees have > 30% cover) — 1 structure: points = 0
If the unit has a Forested class, check if:
☑ The Forested class has 3 out of 5 strata (canopy, sub-canopy, shrubs, herbaceous, moss/ground-cover) that each cover 20% within the Forested polygon

1

H 1.2. Hydroperiods
Check the types of water regimes (hydroperiods) present within the wetland. The water regime has to cover more than 10% of the wetland or ¼ ac to count (*see text for descriptions of hydroperiods*).

☑ Permanently flooded or inundated — 4 or more types present: points = 3
☑ Seasonally flooded or inundated — 3 types present: points = 2
☐ Occasionally flooded or inundated — 2 types present: points = 1
☐ Saturated only — 1 types present: points = 0
☐ Permanently flowing stream or river in, or adjacent to, the wetland
☑ Seasonally flowing stream in, or adjacent to, the wetland
☐ **Lake Fringe wetland** — **2 points**
☐ **Freshwater tidal wetland** — **2 points**

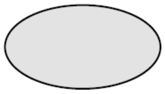
2

H 1.3. Richness of plant species
Count the number of plant species in the wetland that cover at least 10 ft^2.
Different patches of the same species can be combined to meet the size threshold and you do not have to name the species. ***Do not include Eurasian milfoil, reed canarygrass, purple loosestrife, Canadian thistle***

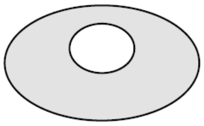
If you counted: > 19 species — points = 2
5 - 19 species — points = 1
< 5 species — points = 0

1

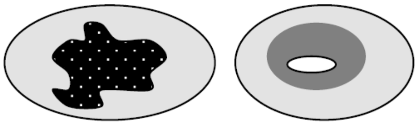
H 1.4. Interspersion of habitats
Decide from the diagrams below whether interspersion among Cowardin plants classes (described in H 1.1), or the classes and unvegetated areas (can include open water or mudflats) is high, moderate, low, or none. *If you have four or more plant classes or three classes and open water, the rating is always high.*



None = 0 points

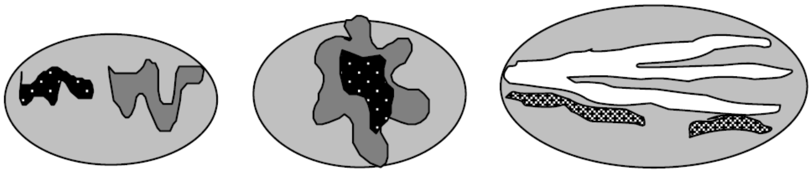


Low = 1 point



Moderate = 2 points

All three diagrams in this row are **HIGH** = 3 points



1

H 1.5. Special habitat features: Check the habitat features that are present in the wetland. *The number of checks is the number of points.*		3
☑ Large, downed, woody debris within the wetland (> 4 in diameter and 6 ft long)		
☑ Standing snags (dbh > 4 in) within the wetland		
☐ Undercut banks are present for at least 6.6 ft (2 m) **and/or** overhanging plants extends at least 3.3 ft (1 m) over a stream (or ditch) in, or contiguous with the wetland, for at least 33 ft (10 m)		
☐ Stable steep banks of fine material that might be used by beaver or muskrat for denning (> 30 degree slope) OR signs of recent beaver activity are present (*cut shrubs or trees that have not yet weathered where wood is exposed*)		
☑ At least ¼ ac of thin-stemmed persistent plants or woody branches are present in areas that are permanently or seasonally inundated (*structures for egg-laying by*		
☐ Invasive plants cover less than 25% of the wetland area in every stratum of plants (*see H 1.1 for list of strata*)		
Total for H 1	Add the points in the boxes above	**8**

Rating of Site Potential If Score is: ☐ **15 - 18 = H** ☑ **7 - 14 = M** ☐ **0 - 6 = L** *Record the rating on the first page*

H 2.0. Does the landscape have the potential to support the habitat function of the site?		
H 2.1 Accessible habitat (include *only habitat that directly abuts wetland unit*). *Calculate:* 0.9 % undisturbed habitat + (0 % moderate & low intensity land uses / 2) = 0.9% If total accessible habitat is:		0
> $^{1}/_{3}$ (33.3%) of 1 km Polygon	points = 3	
20 - 33% of 1 km Polygon	points = 2	
10 - 19% of 1 km Polygon	points = 1	
< 10 % of 1 km Polygon	points = 0	
H 2.2. Undisturbed habitat in 1 km Polygon around the wetland. *Calculate:* 18.1 % undisturbed habitat + (13.8 % moderate & low intensity land uses / 2) = 25%		1
Undisturbed habitat > 50% of Polygon	points = 3	
Undisturbed habitat 10 - 50% and in 1-3 patches	points = 2	
Undisturbed habitat 10 - 50% and > 3 patches	points = 1	
Undisturbed habitat < 10% of 1 km Polygon	points = 0	
H 2.3 Land use intensity in 1 km Polygon: If		-2
> 50% of 1 km Polygon is high intensity land use	points = (-2)	
≤ 50% of 1km Polygon is high intensity	points = 0	
Total for H 2	Add the points in the boxes above	**-1**

Rating of Landscape Potential If Score is: ☐ **4 - 6 = H** ☐ **1 - 3 = M** ☑ **< 1 = L** *Record the rating on the first page*

H 3.0. Is the habitat provided by the site valuable to society?		
H 3.1. Does the site provide habitat for species valued in laws, regulations, or policies? *Choose only the highest score that applies to the wetland being rated*.		1
Site meets ANY of the following criteria:	points = 2	
☐ It has 3 or more priority habitats within 100 m (see next page)		
☐ It provides habitat for Threatened or Endangered species (any plant or animal on the state or federal lists)		
☐ It is mapped as a location for an individual WDFW priority species		
☐ It is a Wetland of High Conservation Value as determined by the Department of Natural Resources		
☐ It has been categorized as an important habitat site in a local or regional comprehensive plan, in a Shoreline Master Plan, or in a watershed plan		
Site has 1 or 2 priority habitats (listed on next page) with in 100m	points = 1	
Site does not meet any of the criteria above	points = 0	

Rating of Value If Score is: ☐ **2 = H** ☑ **1 = M** ☐ **0 = L** *Record the rating on the first page*

WDFW Priority Habitats

Priority habitats listed by WDFW (see complete descriptions of WDFW priority habitats, and the counties in which they can be found, in: Washington Department of Fish and Wildlife. 2008. Priority Habitat and Species List. Olympia, Washington. 177 pp. http://wdfw.wa.gov/publications/00165/wdfw00165.pdf or access the list from here: http://wdfw.wa.gov/conservation/phs/list/

Count how many of the following priority habitats are within 330 ft (100 m) of the wetland unit: ***NOTE****: This question is independent of the land use between the wetland unit and the priority habitat.*

☐ **Aspen Stands**: Pure or mixed stands of aspen greater than 1 ac (0.4 ha).

☐ **Biodiversity Areas and Corridors**: Areas of habitat that are relatively important to various species of native fish and wildlife (*full descriptions in WDFW PHS report*).

☐ **Herbaceous Balds**: Variable size patches of grass and forbs on shallow soils over bedrock.

☑ **Old-growth/Mature forests**: Old-growth west of Cascade crest – Stands of at least 2 tree species, forming a multi-layered canopy with occasional small openings; with at least 8 trees/ac (20 trees/ha) > 32 in (81 cm) dbh or > 200 years of age. Mature forests – Stands with average diameters exceeding 21 in (53 cm) dbh; crown cover may be less than 100%; decay, decadence, numbers of snags, and quantity of large downed material is generally less than that found in old-growth; 80-200 years old west of the Cascade crest.

☐ **Oregon White Oak**: Woodland stands of pure oak or oak/conifer associations where canopy coverage of the oak component is important (*full descriptions in WDFW PHS report p. 158 – see web link above*).

☐ **Riparian**: The area adjacent to aquatic systems with flowing water that contains elements of both aquatic and terrestrial ecosystems which mutually influence each other.

☐ **Westside Prairies**: Herbaceous, non-forested plant communities that can either take the form of a dry prairie or a wet prairie (*full descriptions in WDFW PHS report p. 161 – see web link above*).

☐ **Instream**: The combination of physical, biological, and chemical processes and conditions that interact to provide functional life history requirements for instream fish and wildlife resources.

☐ **Nearshore**: Relatively undisturbed nearshore habitats. These include Coastal Nearshore, Open Coast Nearshore, and Puget Sound Nearshore. (*full descriptions of habitats and the definition of relatively undisturbed are in WDFW report – see web link on previous page*).

☐ **Caves**: A naturally occurring cavity, recess, void, or system of interconnected passages under the earth in soils, rock, ice, or other geological formations and is large enough to contain a human.

☐ **Cliffs**: Greater than 25 ft (7.6 m) high and occurring below 5000 ft elevation.

☐ **Talus**: Homogenous areas of rock rubble ranging in average size 0.5 - 6.5 ft (0.15 - 2.0 m), composed of basalt, andesite, and/or sedimentary rock, including riprap slides and mine tailings. May be associated with cliffs.

☑ **Snags and Logs**: Trees are considered snags if they are dead or dying and exhibit sufficient decay characteristics to enable cavity excavation/use by wildlife. Priority snags have a diameter at breast height of > 20 in (51 cm) in western Washington and are > 6.5 ft (2 m) in height. Priority logs are > 12 in (30 cm) in diameter at the largest end, and > 20 ft (6 m) long.

Note: All vegetated wetlands are by definition a priority habitat but are not included in this list because they are addressed elsewhere.

Wetland name or number WFW-02

CATEGORIZATION BASED ON SPECIAL CHARACTERISTICS

Wetland Type	Category
Check off any criteria that apply to the wetland. List the category when the appropriate criteria are met.	

SC 1.0. Estuarine Wetlands

Does the wetland meet the following criteria for Estuarine wetlands?

☐ The dominant water regime is tidal,

☐ Vegetated, and

☐ With a salinity greater than 0.5 ppt

☐ Yes - Go to **SC 1.1** ☑ No = **Not an estuarine wetland**

SC 1.1. Is the wetland within a National Wildlife Refuge, National Park, National Estuary Reserve, Natural Area Preserve, State Park or Educational, Environmental, or Scientific Reserve designated under WAC 332-30-151?

☐ Yes = **Category I** ☐ No - Go to **SC 1.2**

SC 1.2. Is the wetland unit at least 1 ac in size and meets at least two of the following three conditions?

☐ The wetland is relatively undisturbed (has no diking, ditching, filling, cultivation, grazing, and has less than 10% cover of non-native plant species. (If non-native species are *Spartina*, see page 25)

☐ At least ¾ of the landward edge of the wetland has a 100 ft buffer of shrub, forest, or un-grazed or un-mowed grassland.

☐ The wetland has at least two of the following features: tidal channels, depressions with open water, or contiguous freshwater wetlands.

☐ Yes = **Category I** ☐ No = **Category II**

SC 2.0. Wetlands of High Conservation Value (WHCV)

SC 2.1. Has the WA Department of Natural Resources updated their website to include the list of Wetlands of High Conservation Value?

☑ Yes - Go to **SC 2.2** ☐ No - Go to **SC 2.3**

SC 2.2. Is the wetland listed on the WDNR database as a Wetland of High Conservation Value

☐ Yes = **Category I** ☑ No = **Not WHCV**

SC 2.3. Is the wetland in a Section/Township/Range that contains a Natural Heritage wetland?
http://www1.dnr.wa.gov/nhp/refdesk/datasearch/wnhpwetlands.pdf

☐ Yes - **Contact WNHP/WDNR and to SC 2.4** ☐ No = **Not WHCV**

SC 2.4. Has WDNR identified the wetland within the S/T/R as a Wetland of High Conservation Value and listed it on their website?

☐ Yes = **Category I** ☐ No = **Not WHCV**

SC 3.0. Bogs

Does the wetland (or any part of the unit) meet both the criteria for soils and vegetation in bogs? *Use the key below.* ***If you answer YES you will still need to rate the wetland based on its functions***.

SC 3.1. Does an area within the wetland unit have organic soil horizons, either peats or mucks, that compose 16 in or more of the first 32 in of the soil profile?

☐ Yes - Go to **SC 3.3** ☑ No - Go to **SC 3.2**

SC 3.2. Does an area within the wetland unit have organic soils, either peats or mucks, that are less than 16 in deep over bedrock, or an impermeable hardpan such as clay or volcanic ash, or that are floating on top of a lake or pond?

☐ Yes - Go to **SC 3.3** ☑ No = **Is not a bog**

SC 3.3. Does an area with peats or mucks have more than 70% cover of mosses at ground level, AND at least a 30% cover of plant species listed in Table 4?

☐ Yes = **Is a Category I bog** ☐ No - Go to **SC 3.4**

NOTE: If you are uncertain about the extent of mosses in the understory, you may substitute that criterion by measuring the pH of the water that seeps into a hole dug at least 16 in deep. If the pH is less than 5.0 and the plant species in Table 4 are present, the wetland is a bog.

SC 3.4. Is an area with peats or mucks forested (> 30% cover) with Sitka spruce, subalpine fir, western red cedar, western hemlock, lodgepole pine, quaking aspen, Engelmann spruce, or western white pine, AND any of the species (or combination of species) listed in Table 4 provide more than 30% of the cover under the canopy?

☐ Yes = **Is a Category I bog** ☐ No = **Is not a bog**

SC 4.0. Forested Wetlands

Does the wetland have at least 1 contiguous acre of forest that meets one of these criteria for the WA Department of Fish and Wildlife's forests as priority habitats? ***If you answer YES you will still need to rate the wetland based on its functions.***

☐ **Old-growth forests** (west of Cascade crest): Stands of at least two tree species, forming a multi-layered canopy with occasional small openings; with at least 8 trees/ac (20 trees/ha) that are at least 200 years of age OR have a diameter at breast height (dbh) of 32 in (81 cm) or more.

☐ **Mature forests** (west of the Cascade Crest): Stands where the largest trees are 80-200 years old OR the species that make up the canopy have an average diameter (dbh) exceeding 21 in (53 cm).

☐ Yes = **Category I** ☐ No = **Not a forested wetland for this section**

SC 5.0. Wetlands in Coastal Lagoons

Does the wetland meet all of the following criteria of a wetland in a coastal lagoon?

☐ The wetland lies in a depression adjacent to marine waters that is wholly or partially separated from marine waters by sandbanks, gravel banks, shingle, or, less frequently, rocks

☐ The lagoon in which the wetland is located contains ponded water that is saline or brackish (> 0.5 ppt) during most of the year in at least a portion of the lagoon (*needs to be measured near the bottom*)

☐ Yes - Go to **SC 5.1** ☑No = **Not a wetland in a coastal lagoon**

SC 5.1. Does the wetland meet all of the following three conditions?

☐ The wetland is relatively undisturbed (has no diking, ditching, filling, cultivation, grazing), and has less than 20% cover of aggressive, opportunistic plant species (see list of species on p. 100).

☐ At least ¾ of the landward edge of the wetland has a 100 ft buffer of shrub, forest, or un-grazed or un-mowed grassland.

☐ The wetland is larger than $^{1}/_{10}$ ac (4350 ft^{2})

☐ Yes = **Category I** ☐ No = **Category II**

SC 6.0. Interdunal Wetlands

Is the wetland west of the 1889 line (also called the Western Boundary of Upland Ownership or WBUO)? ***If you answer yes you will still need to rate the wetland based on its habitat functions.***

In practical terms that means the following geographic areas:

☐ Long Beach Peninsula: Lands west of SR 103

☐ Grayland-Westport: Lands west of SR 105

☐ Ocean Shores-Copalis: Lands west of SR 115 and SR 109

☐ Yes - Go to **SC 6.1** ☑No = **Not an interdunal wetland for rating**

SC 6.1. Is the wetland 1 ac or larger and scores an 8 or 9 for the habitat functions on the form (rates H,H,H or H,H,M for the three aspects of function)?

☐ Yes = **Category I** ☐ No - Go to **SC 6.2**

SC 6.2. Is the wetland 1 ac or larger, or is it in a mosaic of wetlands that is 1 ac or larger?

☐ Yes = **Category II** ☐ No - Go to **SC 6.3**

SC 6.3. Is the unit between 0.1 and 1 ac, or is it in a mosaic of wetlands that is between 0.1 and 1 ac?

☐ Yes = **Category III** ☐ No = **Category IV**

Category of wetland based on Special Characteristics

If you answered No for all types, enter "Not Applicable" on Summary Form

RATING SUMMARY – Western Washington

Name of wetland (or ID #): WFW-03 Date of site visit: 10/18/2019

Rated by A. Weiss Trained by Ecology? ☑ Yes ☐ No Date of training Oct-20

HGM Class used for rating Riverine & Fresh Water Tidal Wetland has multiple HGM classes? ☐ Yes ☑ No

NOTE: Form is not complete with out the figures requested (*figures can be combined*).

Screen capture of list of TMDLs for WRIA in which unit is found (from web)	S 3.3	

HGM Classification of Wetland in Western Washington

For questions 1 -7, the criteria described must apply to the entire unit being rated.
If hydrologic criteria listed in each question do not apply to the entire unit being rated, you probably have a unit with multiple HGM classes. In this case, identify which hydrologic criteria in questions 1 - 7 apply, and go to Question 8.

1. Are the water levels in the entire unit usually controlled by tides except during floods?

☑ NO - go to 2 ☐ **YES** - the wetland class is **Tidal Fringe** - go to 1.1

1.1 Is the salinity of the water during periods of annual low flow below 0.5 ppt (parts per thousand)?

☑ **NO - Saltwater Tidal Fringe (Estuarine)** ☐ **YES - Freshwater Tidal Fringe**
If your wetland can be classified as a Freshwater Tidal Fringe use the forms for ***Riverine*** *wetlands. If it is Saltwater Tidal Fringe it is an* ***Estuarine*** *wetland and is not scored. This method* ***cannot*** *be used to score functions for estuarine wetlands.*

2. The entire wetland unit is flat and precipitation is the only source (>90%) of water to it.
Groundwater and surface water runoff are NOT sources of water to the unit.

☑ NO - go to 3 ☐ **YES** - The wetland class is **Flats**
If your wetland can be classified as a Flats wetland, use the form for ***Depressional*** *wetlands.*

3. Does the entire wetland unit **meet all** of the following criteria?
☐ The vegetated part of the wetland is on the shores of a body of permanent open water (without any plants on the surface at any time of the year) at least 20 ac (8 ha) in size;
☐ At least 30% of the open water area is deeper than 6.6 ft (2 m).

☑ NO - go to 4 ☐ **YES** - The wetland class is **Lake Fringe** (Lacustrine Fringe)

4. Does the entire wetland unit **meet all** of the following criteria?
☐ The wetland is on a slope (*slope can be very gradual*),
☐ The water flows through the wetland in one direction (unidirectional) and usually comes from seeps. It may flow subsurface, as sheetflow, or in a swale without distinct banks.
☐ The water leaves the wetland **without being impounded.**

☑ NO - go to 5 ☐ **YES** - The wetland class is **Slope**

NOTE: Surface water does not pond in these type of wetlands except occasionally in very small and shallow depressions or behind hummocks (depressions are usually <3 ft diameter and less than 1 ft deep).

5. Does the entire wetland unit **meet all** of the following criteria?
☐ The unit is in a valley, or stream channel, where it gets inundated by overbank flooding from that stream or river,
☐ The overbank flooding occurs at least once every 2 years.

☐ NO - go to 6 ☑ **YES** - The wetland class is **Riverine**

NOTE: The Riverine unit can contain depressions that are filled with water when the river is not flooding.

6. Is the entire wetland unit in a topographic depression in which water ponds, or is saturated to the surface, at some time during the year? *This means that any outlet, if present, is higher than the interior of the wetland.*

☑ NO - go to 7 ☐ **YES** - The wetland class is **Depressional**

7. Is the entire wetland unit located in a very flat area with no obvious depression and no overbank flooding? The unit does not pond surface water more than a few inches. The unit seems to be maintained by high groundwater in the area. The wetland may be ditched, but has no obvious natural outlet.

☑ NO - go to 8 ☐ **YES** - The wetland class is **Depressional**

8. Your wetland unit seems to be difficult to classify and probably contains several different HGM classes. For example, seeps at the base of a slope may grade into a riverine floodplain, or a small stream within a Depressional wetland has a zone of flooding along its sides. GO BACK AND IDENTIFY WHICH OF THE HYDROLOGIC REGIMES DESCRIBED IN QUESTIONS 1-7 APPLY TO DIFFERENT AREAS IN THE UNIT (make a rough sketch to help you decide). Use the following table to identify the appropriate class to use for the rating system if you have several HGM classes present within the wetland unit being scored.

NOTE: Use this table only if the class that is recommended in the second column represents 10% or more of the total area of the wetland unit being rated. If the area of the HGM class listed in column 2 is less than 10% of the unit; classify the wetland using the class that represents more than 90% of the total area.

HGM classes within the wetland unit being rated	HGM class to use in rating
Slope + Riverine	Riverine
Slope + Depressional	Depressional
Slope + Lake Fringe	Lake Fringe
Depressional + Riverine along stream within boundary of depression	Depressional
Depressional + Lake Fringe	Depressional
Riverine + Lake Fringe	Riverine
Salt Water Tidal Fringe and any other class of freshwater wetland	Treat as ESTUARINE

If you are still unable to determine which of the above criteria apply to your wetland, or if you have ***more than 2 HGM classes*** *within a wetland boundary, classify the wetland as Depressional for the rating.*

NOTES and FIELD OBSERVATIONS:

RIVERINE AND FRESHWATER TIDAL FRINGE WETLANDS

Water Quality Functions - Indicators that the site functions to improve water quality

R 1.0. Does the site have the potential to improve water quality?		
R 1.1. Area of surface depressions within the Riverine wetland that can trap sediments during a flooding event:		2
Depressions cover > $^3/_4$ area of wetland	points = 8	
Depressions cover > ½ area of wetland	points = 4	
Depressions present but cover < ½ area of wetland	points = 2	
No depressions present	points = 0	
R 1.2. Structure of plants in the wetland (areas with >90% cover at person height, **not** Cowardin classes)		6
Trees or shrubs > $^2/_3$ area of the wetland	points = 8	
☑ Trees or shrubs > $^1/_3$ area of the wetland	points = 6	
☐ Herbaceous plants (> 6 in high) > $^2/_3$ area of the wetland	points = 6	
Herbaceous plants (> 6 in high) > $^1/_3$ area of the wetland	points = 3	
Trees, shrubs, and ungrazed herbaceous < $^1/_3$ area of the wetland	points = 0	
Total for R 1	Add the points in the boxes above	**8**

Rating of Site Potential If score is: ☐ **12 - 16 = H** ☑ **6 - 11 = M** ☐ **0 - 5 = L** *Record the rating on the first page*

R 2.0. Does the landscape have the potential to support the water quality function of the site?		
R 2.1. Is the wetland within an incorporated city or within its UGA?	Yes = 2 No = 0	2
R 2.2. Does the contributing basin to the wetland include a UGA or incorporated area?	Yes = 1 No = 0	1
R 2.3. Does at least 10% of the contributing basin contain tilled fields, pastures, or forests that have been clearcut within the last 5 years?	Yes = 1 No = 0	0
R 2.4. Is > 10% of the area within 150 ft of the wetland in land uses that generate pollutants?	Yes = 1 No = 0	1
R 2.5. Are there other sources of pollutants coming into the wetland that are not listed in questions R 2.1 - R 2.4? Other Sources	Yes = 1 No = 0	0
Total for R 2	Add the points in the boxes above	**4**

Rating of Landscape Potential If score is: ☑ **3 - 6 = H** ☐ **1 or 2 = M** ☐ **0 = L** *Record the rating on the first page*

R 3.0. Is the water quality improvement provided by the site valuable to society?		
R 3.1. Is the wetland along a stream or river that is on the 303(d) list or on a tributary that drains to one within 1 mi?	Yes = 1 No = 0	0
R 3.2. Is the wetland along a stream or river that has TMDL limits for nutrients, toxics, or pathogens?	Yes = 1 No = 0	0
R 3.3. Has the site been identified in a watershed or local plan as important for maintaining water quality? (*answer YES if there is a TMDL for the drainage in which the unit is found*)	Yes = 2 No = 0	0
Total for R 3	Add the points in the boxes above	**0**

Rating of Value If score is: ☐ **2 - 4 = H** ☐ **1 = M** ☑ **0 = L** *Record the rating on the first page*

RIVERINE AND FRESHWATER TIDAL FRINGE WETLANDS

Hydrologic Functions - Indicators that site functions to reduce flooding and stream erosion

R 4.0. Does the site have the potential to reduce flooding and erosion?		
R 4.1. Characteristics of the overbank storage the wetland provides: *Estimate the average width of the wetland perpendicular to the direction of the flow and the width of the stream or river channel (distance between banks). Calculate the ratio: (average width of wetland)/(average width of stream between banks).*		
If the ratio is more than 20	points = 9	2
If the ratio is 10 - 20	points = 6	
If the ratio is 5 - < 10	points = 4	
If the ratio is 1 - < 5	points = 2	
If the ratio is < 1	points = 1	
R 4.2. Characteristics of plants that slow down water velocities during floods: *Treat large woody debris as forest or shrub. Choose the points appropriate for the best description (polygons need to have >90% cover at person height. These are* *NOT Cowardin* *classes*).		7
Forest or shrub for > $^{1}/_{3}$ area OR emergent plants > $^{2}/_{3}$ area	points = 7	
Forest or shrub for > $^{1}/_{10}$ area OR emergent plants > $^{1}/_{3}$ area	points = 4	
Plants do not meet above criteria	points = 0	
Total for R 4	Add the points in the boxes above	**9**

Rating of Site Potential If score is: ☐ **12 - 16 = H** ☑ **6 - 11 = M** ☐ **0 - 5 = L** *Record the rating on the first page*

R 5.0. Does the landscape have the potential to support the hydrologic functions of the site?		
R 5.1. Is the stream or river adjacent to the wetland downcut?	Yes = 0 No = 1	1
R 5.2. Does the up-gradient watershed include a UGA or incorporated area?	Yes = 1 No = 0	1
R 5.3 Is the up-gradient stream or river controlled by dams?	Yes = 0 No = 1	1
Total for R 5	Add the points in the boxes above	**3**

Rating of Landscape Potential If score is: ☑ **3 = H** ☐ **1 or 2 = M** ☐ **0 = L** *Record the rating on the first page*

R 6.0. Are the hydrologic functions provided by the site valuable to society?		
R 6.1. Distance to the nearest areas downstream that have flooding problems? *Choose the description that best fits the site.*		
The sub-basin immediately down-gradient of the wetland has flooding problems that result in damage to human or natural resources (e.g., houses or salmon redds)	points = 2	1
Surface flooding problems are in a sub-basin farther down-gradient	points = 1	
No flooding problems anywhere downstream	points = 0	
R 6.2. Has the site been identified as important for flood storage or flood conveyance in a regional flood control plan?	Yes = 2 No = 0	0
Total for R 6	Add the points in the boxes above	**1**

Rating of Value If score is: ☐ **2 - 4 = H** ☑ **1 = M** ☐ **0 = L** *Record the rating on the first page*

These questions apply to wetlands of all HGM classes.

HABITAT FUNCTIONS - Indicators that site functions to provide important habitat

H 1.0. Does the site have the potential to provide habitat?

H 1.1. Structure of plant community: *Indicators are Cowardin classes and strata within the Forested class.* Check the Cowardin plant classes in the wetland. *Up to 10 patches may be combined for each class to meet the threshold of ¼ ac or more than 10% of the unit if it is smaller than 2.5 ac. Add the number of structures checked.*

☐ Aquatic bed
☐ Emergent
☐ Scrub-shrub (areas where shrubs have > 30% cover)
☑ Forested (areas where trees have > 30% cover)
If the unit has a Forested class, check if:
☐ The Forested class has 3 out of 5 strata (canopy, sub-canopy, shrubs, herbaceous, moss/ground-cover) that each cover 20% within the Forested polygon

4 structures or more: points = 4
3 structures: points = 2
2 structures: points - 1
1 structure: points = 0

0

H 1.2. Hydroperiods
Check the types of water regimes (hydroperiods) present within the wetland. The water regime has to cover more than 10% of the wetland or ¼ ac to count (*see text for descriptions of hydroperiods*).

☐ Permanently flooded or inundated
☐ Seasonally flooded or inundated
☑ Occasionally flooded or inundated
☑ Saturated only
☐ Permanently flowing stream or river in, or adjacent to, the wetland
☑ Seasonally flowing stream in, or adjacent to, the wetland
☐ **Lake Fringe wetland** **2 points**
☐ **Freshwater tidal wetland** **2 points**

4 or more types present: points = 3
3 types present: points = 2
2 types present: points = 1
1 types present: points = 0

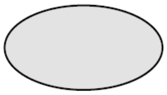
2

H 1.3. Richness of plant species
Count the number of plant species in the wetland that cover at least 10 ft^2.
Different patches of the same species can be combined to meet the size threshold and you do not have to name the species. ***Do not include Eurasian milfoil, reed canarygrass, purple loosestrife, Canadian thistle***

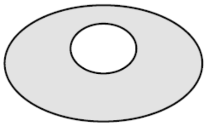
If you counted:	> 19 species	points = 2
	5 - 19 species	points = 1
	< 5 species	points = 0

1

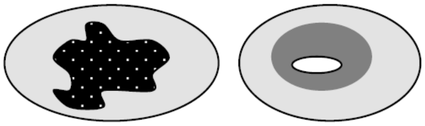
H 1.4. Interspersion of habitats
Decide from the diagrams below whether interspersion among Cowardin plants classes (described in H 1.1), or the classes and unvegetated areas (can include open water or mudflats) is high, moderate, low, or none. *If you have four or more plant classes or three classes and open water, the rating is always high.*



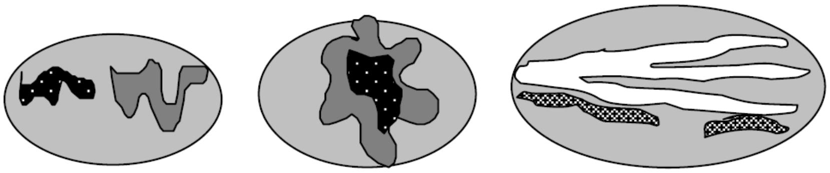
None = 0 points



Low = 1 point



Moderate = 2 points



All three diagrams in this row are **HIGH** = 3 points

1

H 1.5. Special habitat features: Check the habitat features that are present in the wetland. *The number of checks is the number of points.* ☑ Large, downed, woody debris within the wetland (> 4 in diameter and 6 ft long) ☑ Standing snags (dbh > 4 in) within the wetland ☑ Undercut banks are present for at least 6.6 ft (2 m) **and/or** overhanging plants extends at least 3.3 ft (1 m) over a stream (or ditch) in, or contiguous with the wetland, for at least 33 ft (10 m) ☐ Stable steep banks of fine material that might be used by beaver or muskrat for denning (> 30 degree slope) OR signs of recent beaver activity are present (*cut shrubs or trees that have not yet weathered where wood is exposed*) ☐ At least ¼ ac of thin-stemmed persistent plants or woody branches are present in areas that are permanently or seasonally inundated (*structures for egg-laying by amphibians*) ☐ Invasive plants cover less than 25% of the wetland area in every stratum of plants (*see H 1.1 for list of strata*)	3
Total for H 1 Add the points in the boxes above	**7**

Rating of Site Potential If Score is: ☐ **15 - 18 = H** ☑ **7 - 14 = M** ☐ **0 - 6 = L** *Record the rating on the first page*

H 2.0. Does the landscape have the potential to support the habitat function of the site?	
H 2.1 Accessible habitat (include *only habitat that directly abuts wetland unit*). *Calculate:* 2.7 % undisturbed habitat + (1.3 % moderate & low intensity land uses / 2) = 3.35% If total accessible habitat is: > $^1/_3$ (33.3%) of 1 km Polygon points = 3 20 - 33% of 1 km Polygon points = 2 10 - 19% of 1 km Polygon points = 1 < 10 % of 1 km Polygon points = 0	0
H 2.2. Undisturbed habitat in 1 km Polygon around the wetland. *Calculate:* 27.9 % undisturbed habitat + (19.7 % moderate & low intensity land uses / 2) = 37.75% Undisturbed habitat > 50% of Polygon points = 3 Undisturbed habitat 10 - 50% and in 1-3 patches points = 2 Undisturbed habitat 10 - 50% and > 3 patches points = 1 Undisturbed habitat < 10% of 1 km Polygon points = 0	1
H 2.3 Land use intensity in 1 km Polygon: If > 50% of 1 km Polygon is high intensity land use points = (-2) ≤ 50% of 1km Polygon is high intensity points = 0	-2
Total for H 2 Add the points in the boxes above	**-1**

Rating of Landscape Potential If Score is: ☐ **4 - 6 = H** ☐ **1 - 3 = M** ☑ **< 1 = L** *Record the rating on the first page*

H 3.0. Is the habitat provided by the site valuable to society?	
H 3.1. Does the site provide habitat for species valued in laws, regulations, or policies? *Choose only the highest score that applies to the wetland being rated*. Site meets ANY of the following criteria: points = 2 ☑ It has 3 or more priority habitats within 100 m (see next page) ☐ It provides habitat for Threatened or Endangered species (any plant or animal on the state or federal lists) ☐ It is mapped as a location for an individual WDFW priority species ☐ It is a Wetland of High Conservation Value as determined by the Department of Natural Resources ☐ It has been categorized as an important habitat site in a local or regional comprehensive plan, in a Shoreline Master Plan, or in a watershed plan Site has 1 or 2 priority habitats (listed on next page) with in 100m points = 1 Site does not meet any of the criteria above points = 0	2

Rating of Value If Score is: ☑ **2 = H** ☐ **1 = M** ☐ **0 = L** *Record the rating on the first page*

WDFW Priority Habitats

Priority habitats listed by WDFW (see complete descriptions of WDFW priority habitats, and the counties in which they can be found, in: Washington Department of Fish and Wildlife. 2008. Priority Habitat and Species List. Olympia, Washington. 177 pp.
http://wdfw.wa.gov/publications/00165/wdfw00165.pdf or access the list from here:
http://wdfw.wa.gov/conservation/phs/list/

Count how many of the following priority habitats are within 330 ft (100 m) of the wetland unit: ***NOTE**: This question is independent of the land use between the wetland unit and the priority habitat.*

☐ **Aspen Stands**: Pure or mixed stands of aspen greater than 1 ac (0.4 ha).

☐ **Biodiversity Areas and Corridors**: Areas of habitat that are relatively important to various species of native fish and wildlife (*full descriptions in WDFW PHS report*).

☐ **Herbaceous Balds**: Variable size patches of grass and forbs on shallow soils over bedrock.

☐ **Old-growth/Mature forests**: Old-growth west of Cascade crest – Stands of at least 2 tree species, forming a multi-layered canopy with occasional small openings; with at least 8 trees/ac (20 trees/ha) > 32 in (81 cm) dbh or > 200 years of age. Mature forests – Stands with average diameters exceeding 21 in (53 cm) dbh; crown cover may be less than 100%; decay, decadence, numbers of snags, and quantity of large downed material is generally less than that found in old-growth; 80-200 years old west of the Cascade crest.

☐ **Oregon White Oak**: Woodland stands of pure oak or oak/conifer associations where canopy coverage of the oak component is important (*full descriptions in WDFW PHS report p. 158 – see web link above*).

☑ **Riparian**: The area adjacent to aquatic systems with flowing water that contains elements of both aquatic and terrestrial ecosystems which mutually influence each other.

☐ **Westside Prairies**: Herbaceous, non-forested plant communities that can either take the form of a dry prairie or a wet prairie (*full descriptions in WDFW PHS report p. 161 – see web link above*).

☑ **Instream**: The combination of physical, biological, and chemical processes and conditions that interact to provide functional life history requirements for instream fish and wildlife resources.

☐ **Nearshore**: Relatively undisturbed nearshore habitats. These include Coastal Nearshore, Open Coast Nearshore, and Puget Sound Nearshore. (*full descriptions of habitats and the definition of relatively undisturbed are in WDFW report – see web link on previous page*).

☐ **Caves**: A naturally occurring cavity, recess, void, or system of interconnected passages under the earth in soils, rock, ice, or other geological formations and is large enough to contain a human.

☐ **Cliffs**: Greater than 25 ft (7.6 m) high and occurring below 5000 ft elevation.

☐ **Talus**: Homogenous areas of rock rubble ranging in average size 0.5 - 6.5 ft (0.15 - 2.0 m), composed of basalt, andesite, and/or sedimentary rock, including riprap slides and mine tailings. May be associated with cliffs.

☑ **Snags and Logs**: Trees are considered snags if they are dead or dying and exhibit sufficient decay characteristics to enable cavity excavation/use by wildlife. Priority snags have a diameter at breast height of > 20 in (51 cm) in western Washington and are > 6.5 ft (2 m) in height. Priority logs are > 12 in (30 cm) in diameter at the largest end, and > 20 ft (6 m) long.

Note: All vegetated wetlands are by definition a priority habitat but are not included in this list because they are addressed elsewhere.

CATEGORIZATION BASED ON SPECIAL CHARACTERISTICS

Wetland Type *Check off any criteria that apply to the wetland. List the category when the appropriate criteria are met.*	**Category**

SC 1.0. Estuarine Wetlands

Does the wetland meet the following criteria for Estuarine wetlands?

☐ The dominant water regime is tidal,
☐ Vegetated, and
☐ With a salinity greater than 0.5 ppt

☐ Yes - Go to **SC 1.1** ☑ No = **Not an estuarine wetland**

SC 1.1. Is the wetland within a National Wildlife Refuge, National Park, National Estuary Reserve, Natural Area Preserve, State Park or Educational, Environmental, or Scientific Reserve designated under WAC 332-30-151?

☐ Yes = **Category I** ☑ No - Go to **SC 1.2**

SC 1.2. Is the wetland unit at least 1 ac in size and meets at least two of the following three conditions?

☐ The wetland is relatively undisturbed (has no diking, ditching, filling, cultivation, grazing, and has less than 10% cover of non-native plant species. (If non-native species are *Spartina* , see page 25)
☐ At least ¾ of the landward edge of the wetland has a 100 ft buffer of shrub, forest, or un-grazed or un-mowed grassland.
☐ The wetland has at least two of the following features: tidal channels, depressions with open water, or contiguous freshwater wetlands.

☐ Yes = **Category I** ☐ No = **Category II**

SC 2.0. Wetlands of High Conservation Value (WHCV)

SC 2.1. Has the WA Department of Natural Resources updated their website to include the list of Wetlands of High Conservation Value?

☐ Yes - Go to **SC 2.2** ☑ No - Go to **SC 2.3**

SC 2.2. Is the wetland listed on the WDNR database as a Wetland of High Conservation Value?

☐ Yes = **Category I** ☑ No = **Not WHCV**

SC 2.3. Is the wetland in a Section/Township/Range that contains a Natural Heritage wetland?
http://www1.dnr.wa.gov/nhp/refdesk/datasearch/wnhpwetlands.pdf

☐ Yes - **Contact WNHP/WDNR and to SC 2.4** ☐ No = **Not WHCV**

SC 2.4. Has WDNR identified the wetland within the S/T/R as a Wetland of High Conservation Value and listed it on their website?

☐ Yes = **Category I** ☐ No = **Not WHCV**

SC 3.0. Bogs

Does the wetland (or any part of the unit) meet both the criteria for soils and vegetation in bogs? *Use the key below.* ***If you answer YES you will still need to rate the wetland based on its functions*** *.*

SC 3.1. Does an area within the wetland unit have organic soil horizons, either peats or mucks, that compose 16 in or more of the first 32 in of the soil profile?

☐ Yes - Go to **SC 3.3** ☑ No - Go to **SC 3.2**

SC 3.2. Does an area within the wetland unit have organic soils, either peats or mucks, that are less than 16 in deep over bedrock, or an impermeable hardpan such as clay or volcanic ash, or that are floating on top of a lake or pond?

☐ Yes - Go to **SC 3.3** ☑ No = **Is not a bog**

SC 3.3. Does an area with peats or mucks have more than 70% cover of mosses at ground level, AND at least a 30% cover of plant species listed in Table 4?

☐ Yes = **Is a Category I bog** ☐ No - Go to **SC 3.4**

NOTE: If you are uncertain about the extent of mosses in the understory, you may substitute that criterion by measuring the pH of the water that seeps into a hole dug at least 16 in deep. If the pH is less than 5.0 and the plant species in Table 4 are present, the wetland is a bog.

SC 3.4. Is an area with peats or mucks forested (> 30% cover) with Sitka spruce, subalpine fir, western red cedar, western hemlock, lodgepole pine, quaking aspen, Engelmann spruce, or western white pine, AND any of the species (or combination of species) listed in Table 4 provide more than 30% of the cover under the canopy?

☐ Yes = **Is a Category I bog** ☐ No = **Is not a bog**

SC 4.0. Forested Wetlands

Does the wetland have at least 1 contiguous acre of forest that meets one of these criteria for the WA Department of Fish and Wildlife's forests as priority habitats? ***If you answer YES you will still need to rate the wetland based on its functions.***

☐ **Old-growth forests** (west of Cascade crest): Stands of at least two tree species, forming a multi-layered canopy with occasional small openings; with at least 8 trees/ac (20 trees/ha) that are at least 200 years of age OR have a diameter at breast height (dbh) of 32 in (81 cm) or more.

☐ **Mature forests** (west of the Cascade Crest): Stands where the largest trees are 80- 200 years old OR the species that make up the canopy have an average diameter (dbh) exceeding 21 in (53 cm).

☐ Yes = **Category I** ☑ No = **Not a forested wetland for this section**

SC 5.0. Wetlands in Coastal Lagoons

Does the wetland meet all of the following criteria of a wetland in a coastal lagoon?

☐ The wetland lies in a depression adjacent to marine waters that is wholly or partially separated from marine waters by sandbanks, gravel banks, shingle, or, less frequently, rocks

☐ The lagoon in which the wetland is located contains ponded water that is saline or brackish (> 0.5 ppt) during most of the year in at least a portion of the lagoon (*needs to be measured near the bottom*)

☐ Yes - Go to **SC 5.1** ☑ No = **Not a wetland in a coastal lagoon**

SC 5.1. Does the wetland meet all of the following three conditions?

☐ The wetland is relatively undisturbed (has no diking, ditching, filling, cultivation, grazing), and has less than 20% cover of aggressive, opportunistic plant species (see list of species on p. 100).

☐ At least ¾ of the landward edge of the wetland has a 100 ft buffer of shrub, forest, or un-grazed or un-mowed grassland.

☐ The wetland is larger than $^{1}/_{10}$ ac (4350 ft^2)

☐ Yes = **Category I** ☐ No = **Category II**

SC 6.0. Interdunal Wetlands

Is the wetland west of the 1889 line (also called the Western Boundary of Upland Ownership or WBUO)? ***If you answer yes you will still need to rate the wetland based on its habitat functions.***

In practical terms that means the following geographic areas:

☐ Long Beach Peninsula: Lands west of SR 103
☐ Grayland-Westport: Lands west of SR 105
☐ Ocean Shores-Copalis: Lands west of SR 115 and SR 109

☐ Yes - Go to **SC 6.1** ☑ No = **Not an interdunal wetland for rating**

SC 6.1. Is the wetland 1 ac or larger and scores an 8 or 9 for the habitat functions on the form (rates H,H,H or H,H,M for the three aspects of function)?

☐ Yes = **Category I** ☐ No - Go to **SC 6.2**

SC 6.2. Is the wetland 1 ac or larger, or is it in a mosaic of wetlands that is 1 ac or larger?

☐ Yes = **Category II** ☐ No - Go to **SC 6.3**

SC 6.3. Is the unit between 0.1 and 1 ac, or is it in a mosaic of wetlands that is between 0.1 and 1 ac?

☐ Yes = **Category III** ☐ No = **Category IV**

Category of wetland based on Special Characteristics

If you answered No for all types, enter "Not Applicable" on Summary Form

RATING SUMMARY – Western Washington

Name of wetland (or ID #): WFW-04 Date of site visit: 10/18/2019

Rated by A. Weiss Trained by Ecology? ☑ Yes ☐ No Date of training Oct. 2020

HGM Class used for rating Depressional & Flats Wetland has multiple HGM classes? ☐ Yes ☑ No

NOTE: Form is not complete with out the figures requested (*figures can be combined*).

Maps and Figures required to answer questions correctly for Western Washington

Depressional Wetlands

Map of:	**To answer questions:**	**Figure #**
Cowardin plant classes	D 1.3, H 1.1, H 1.4	
Hydroperiods	D 1.4, H 1.2	
Location of outlet (*can be added to map of hydroperiods*)	D 1.1, D 4.1	
Boundary of area within 150 ft of the wetland (*can be added to another figure*)	D 2.2, D 5.2	
Map of the contributing basin	D 4.3, D 5.3	
1 km Polygon: Area that extends 1 km from entire wetland edge - including polygons for accessible habitat and undisturbed habitat	H 2.1, H 2.2, H 2.3	
Screen capture of map of 303(d) listed waters in basin (from Ecology website)	D 3.1, D 3.2	
Screen capture of list of TMDLs for WRIA in which unit is found (from web)	D 3.3	

Riverine Wetlands

Map of:	**To answer questions:**	**Figure #**
Cowardin plant classes	H 1.1, H 1.4	
Hydroperiods	H 1.2	
Ponded depressions	R 1.1	
Boundary of area within 150 ft of the wetland (*can be added to another figure*)	R 2.4	
Plant cover of trees, shrubs, and herbaceous plants	R 1.2, R 4.2	
Width of unit vs. width of stream (*can be added to another figure*)	R 4.1	
Map of the contributing basin	R 2.2, R 2.3, R 5.2	
1 km Polygon: Area that extends 1 km from entire wetland edge - including polygons for accessible habitat and undisturbed habitat	H 2.1, H 2.2, H 2.3	
Screen capture of map of 303(d) listed waters in basin (from Ecology website)	R 3.1	
Screen capture of list of TMDLs for WRIA in which unit is found (from web)	R 3.2, R 3.3	

Lake Fringe Wetlands

Map of:	**To answer questions:**	**Figure #**
Cowardin plant classes	L 1.1, L 4.1, H 1.1, H 1.4	
Plant cover of trees, shrubs, and herbaceous plants	L 1.2	
Boundary of area within 150 ft of the wetland (*can be added to another figure*)	L 2.2	
1 km Polygon: Area that extends 1 km from entire wetland edge - including polygons for accessible habitat and undisturbed habitat	H 2.1, H 2.2, H 2.3	
Screen capture of map of 303(d) listed waters in basin (from Ecology website)	L 3.1, L 3.2	
Screen capture of list of TMDLs for WRIA in which unit is found (from web)	L 3.3	

Slope Wetlands

Map of:	**To answer questions:**	**Figure #**
Cowardin plant classes	H 1.1, H 1.4	
Hydroperiods	H 1.2	
Plant cover of **dense** trees, shrubs, and herbaceous plants	S 1.3	
Plant cover of **dense, rigid** trees, shrubs, and herbaceous plants (*can be added to another figure*)	S 4.1	
Boundary of area within 150 ft of the wetland (*can be added to another figure*)	S 2.1, S 5.1	
1 km Polygon: Area that extends 1 km from entire wetland edge - including polygons for accessible habitat and undisturbed habitat	H 2.1, H 2.2, H 2.3	
Screen capture of map of 303(d) listed waters in basin (from Ecology website)	S 3.1, S 3.2	
Screen capture of list of TMDLs for WRIA in which unit is found (from web)	S 3.3	

HGM Classification of Wetland in Western Washington

For questions 1 -7, the criteria described must apply to the entire unit being rated.
If hydrologic criteria listed in each question do not apply to the entire unit being rated, you probably have a unit with multiple HGM classes. In this case, identify which hydrologic criteria in questions 1 - 7 apply, and go to Question 8.

1. Are the water levels in the entire unit usually controlled by tides except during floods?

☑ NO - go to 2 ☐ **YES** - the wetland class is **Tidal Fringe** - go to 1.1

1.1 Is the salinity of the water during periods of annual low flow below 0.5 ppt (parts per thousand)?

☐ **NO - Saltwater Tidal Fringe (Estuarine)** ☐ **YES - Freshwater Tidal Fringe**

If your wetland can be classified as a Freshwater Tidal Fringe use the forms for ***Riverine*** *wetlands. If it is Saltwater Tidal Fringe it is an* ***Estuarine*** *wetland and is not scored. This method* ***cannot*** *be used to score functions for estuarine wetlands.*

2. The entire wetland unit is flat and precipitation is the only source (>90%) of water to it.
Groundwater and surface water runoff are NOT sources of water to the unit.

☑ NO - go to 3 ☐ **YES** - The wetland class is **Flats**

If your wetland can be classified as a Flats wetland, use the form for ***Depressional*** *wetlands.*

3. Does the entire wetland unit **meet all** of the following criteria?

☐ The vegetated part of the wetland is on the shores of a body of permanent open water (without any plants on the surface at any time of the year) at least 20 ac (8 ha) in size;
☐ At least 30% of the open water area is deeper than 6.6 ft (2 m).

☑ NO - go to 4 ☐ **YES** - The wetland class is **Lake Fringe** (Lacustrine Fringe)

4. Does the entire wetland unit **meet all** of the following criteria?

☐ The wetland is on a slope (*slope can be very gradual*),
☐ The water flows through the wetland in one direction (unidirectional) and usually comes from seeps. It may flow subsurface, as sheetflow, or in a swale without distinct banks.
☐ The water leaves the wetland **without being impounded.**

☑ NO - go to 5 ☐ **YES** - The wetland class is **Slope**

NOTE: Surface water does not pond in these type of wetlands except occasionally in very small and shallow depressions or behind hummocks (depressions are usually <3 ft diameter and less than 1 ft deep).

5. Does the entire wetland unit **meet all** of the following criteria?

☐ The unit is in a valley, or stream channel, where it gets inundated by overbank flooding from that stream or river,
☐ The overbank flooding occurs at least once every 2 years.

☑ NO - go to 6 ☐ **YES** - The wetland class is **Riverine**

NOTE: The Riverine unit can contain depressions that are filled with water when the river is not flooding.

6. Is the entire wetland unit in a topographic depression in which water ponds, or is saturated to the surface, at some time during the year? *This means that any outlet, if present, is higher than the interior of the wetland.*

☐ NO - go to 7 ☑ **YES** - The wetland class is **Depressional**
